2013 Fall Meeting of the APS Division of Nuclear Physics

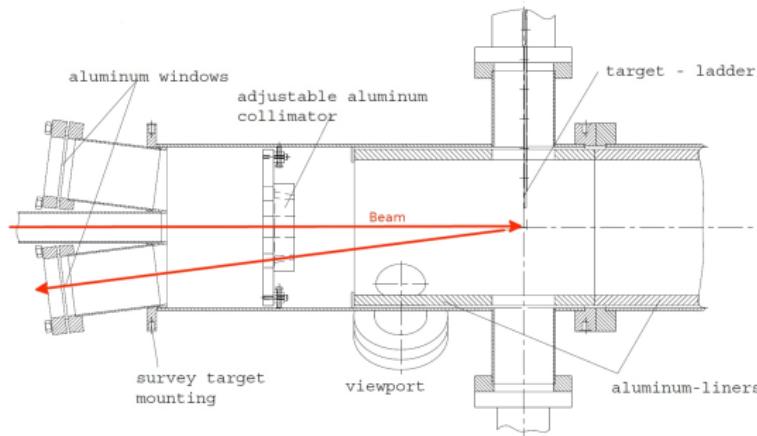

# Mott Polarimeter Location

- Measures transverse polarization in the injector, just before the main accelerator.
- In use for over 15 years.
- New effort at understanding and improving is underway.

# Polarimeter Overview

- Measures elastic scattering asymmetry,  $A_{\text{exp}}$ , in thin ( $d = 0.01\text{-}1.0 \mu\text{m}$ ) Au foil.
- $P = \frac{A_{\text{exp}}}{S_{\text{eff}}(\theta, d)}$

Al collimator defines  
 $\theta = 172.6^\circ \pm 0.45^\circ$  and  
 $\delta\Omega = 0.21 \text{ msr.}$

Typical Parameter Ranges	
$I_{\text{beam}}$	$\leq 1.5 \mu\text{A}$
Beam Energy	2 MeV - 10 MeV
Event Rate	$\leq 5 \text{ kHz}$
Spin Flip Rate	30 Hz - 960 Hz

# Mott Scattering Asymmetry

$e^-$  – nucleus scattering:

$$\sigma(\theta) = I(\theta) [1 + S(\theta) \mathbf{P} \cdot \mathbf{n}]$$

with  $\mathbf{n} = \frac{\mathbf{k} \times \mathbf{k}'}{|\mathbf{k} \times \mathbf{k}'|}$ . If  $\mathbf{P}$  is horizontal, measure an up-down asymmetry:

$$A_{UD} = \frac{\sigma_U - \sigma_D}{\sigma_U + \sigma_D} = S(\theta) P.$$

Use the cross-ratio method:

$$A_{UD} = \frac{1 - r}{1 + r}$$

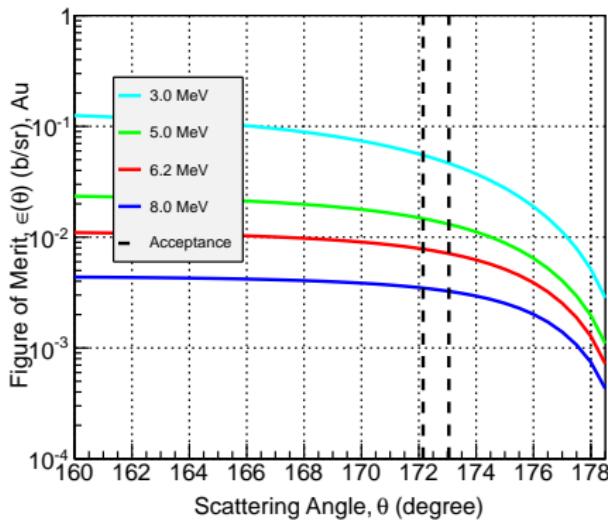

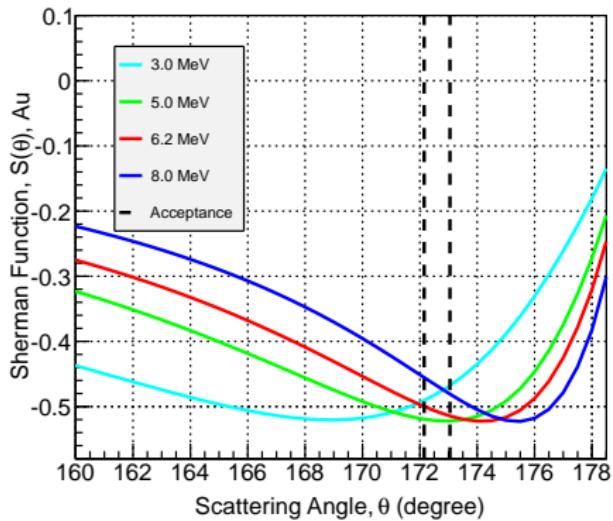

with

$$r = \sqrt{\frac{N_U^\uparrow N_D^\downarrow}{N_U^\downarrow N_D^\uparrow}}.$$

Insensitive to false asymmetries at **all orders** from detector solid angle and efficiency, beam current, and target thickness.

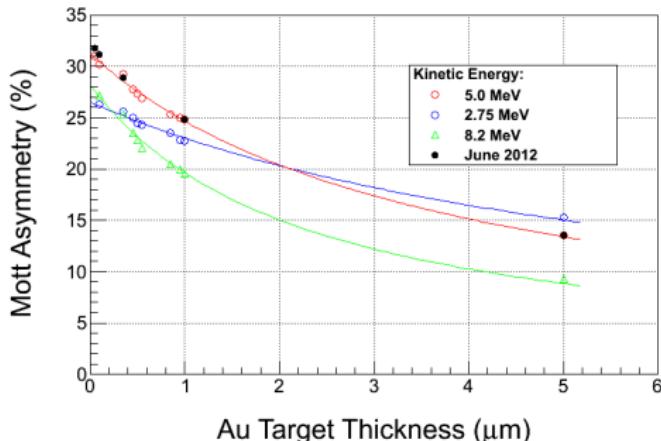

To **first order** from polarization differences and scattering angle.

# Polarimeter Optimization

- Designed to run at 5 MeV.
- Figure of Merit,  $\epsilon(\theta) = I(\theta)S(\theta)^2$ , is inversely related to  $\delta A/A(t)$ .
- Can measure to  $\delta A \approx 0.5\%$  stat. using typical setup ( $1\mu\text{A}$  on  $1\mu\text{m}$  Au) in 5 minutes.

# Multiple Scattering and Effective Sherman Function

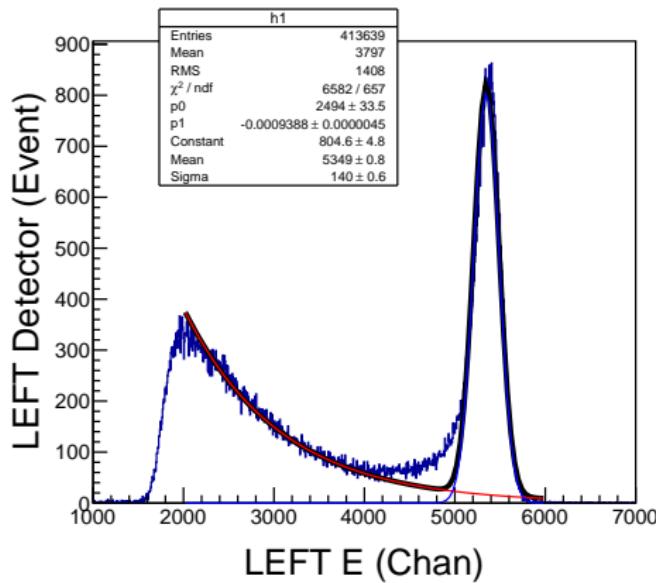

Error bars smaller than points  
Curves are fits

$$A(d) = PS_{\text{eff}}(\theta, d)$$
$$= \frac{PS(\theta)}{1 + \alpha d}$$

- Paper in 2000 quoted 1.1% uncertainty for  $S(\theta)$ .
- Uncertainty in  $S_{\text{eff}}(\theta, d)$  dominant systematic error.
- GEANT4 Simulation with theory support will improve this.

# Detector Spectrum

Three main components:

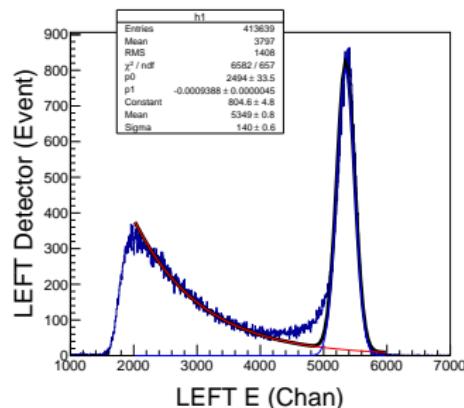

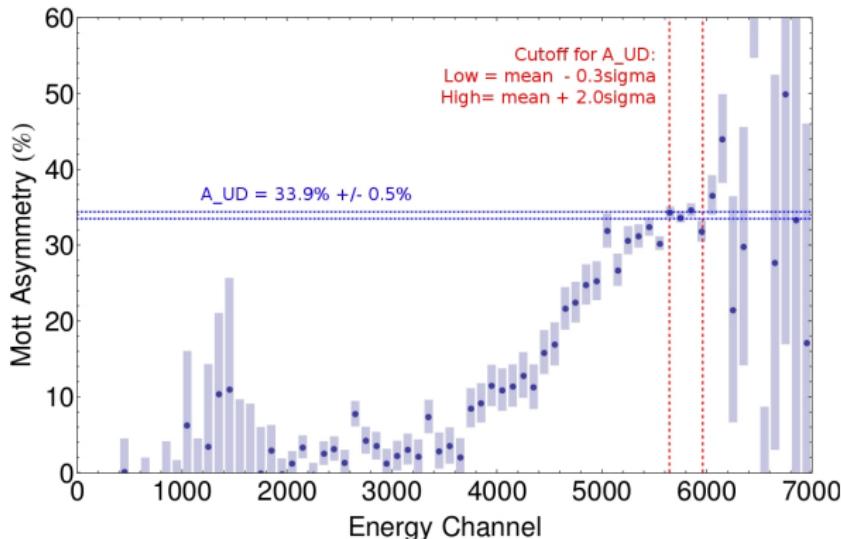

- ① Background
- ② Low Energy Shoulder (4000 - 5000)
- ③ Elastic Peak

Data taken with  $1.25 \mu\text{A}$  on  $1 \mu\text{m}$  Au.

Asymmetry calculated with events in range:

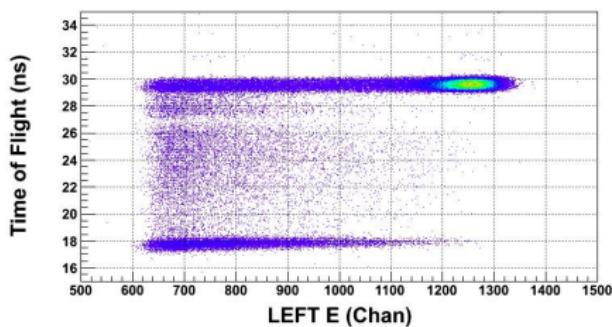

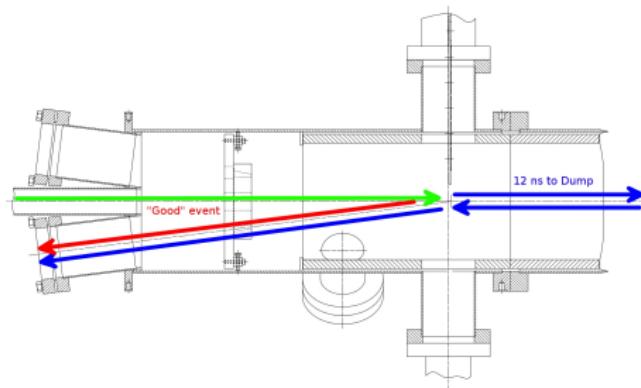

$$[E_{\text{mean}} - 0.3\sigma, E_{\text{mean}} + 2\sigma] = [5391, 5629]$$

# Asymmetry Vs. Energy

- Shoulder contains good events.
- Simulation points to elastic  $e^-$  with radiative losses in detectors.

# Beam Dump Background

- Dump is 1" Al plate.
- Can use TDC to discriminate at low rep rate.
- $\approx 50\%$  of events NOT from target on  $1 \mu\text{m}$
- 2% of events in asymmetry on  $1 \mu\text{m}$  Au.
- Need to determine dilution factor and asymmetry for this background.

# Future Work

## ① GEANT4 Simulation:

- ▶ Describe “shoulder” events
- ▶ Identify and reduce backgrounds
- ▶ Provide numerical support for  $S_{\text{eff}}(\theta, d)$

## ② Hardware update:

- ▶ Be dump plate to reduce backgrounds
- ▶ Higher current running
- ▶ New target ladder and inventory

## ③ Precision tests:

- ▶ Determination of background dilutions and asymmetries
- ▶ Improved extrapolation for  $S_{\text{eff}}(\theta, d)$
