- Extra gain (x100) by measuring time inverse reaction
- Target density up to  $\times 10^6$  higher than conventional targets
- Superheated liquid will nucleate from  $\alpha$  and  ${}^{12}\text{C}$  recoils
- Electromagnetic debris (degraded electrons and gammas, or positrons) that escape the collimator/electron beam do NOT trigger nucleation (detector is insensitive to  $\gamma$ -rays by at least 1 part in  $10^{11}$ ).

# BEAM REQUIREMENTS

## I. Beam Properties at Radiator:

Beam Kinetic Energy, (MeV)	3.0 – 8.5
Beam Current ( $\mu\text{A}$ )	0.01 – 100
Absolute Beam Energy	0.1%
Relative Beam Energy	0.05%?
Energy Resolution (Spread), $\sigma_T/T$	0.06%
Beam Size, $\sigma_{x,y}$ (mm)	1 – 2

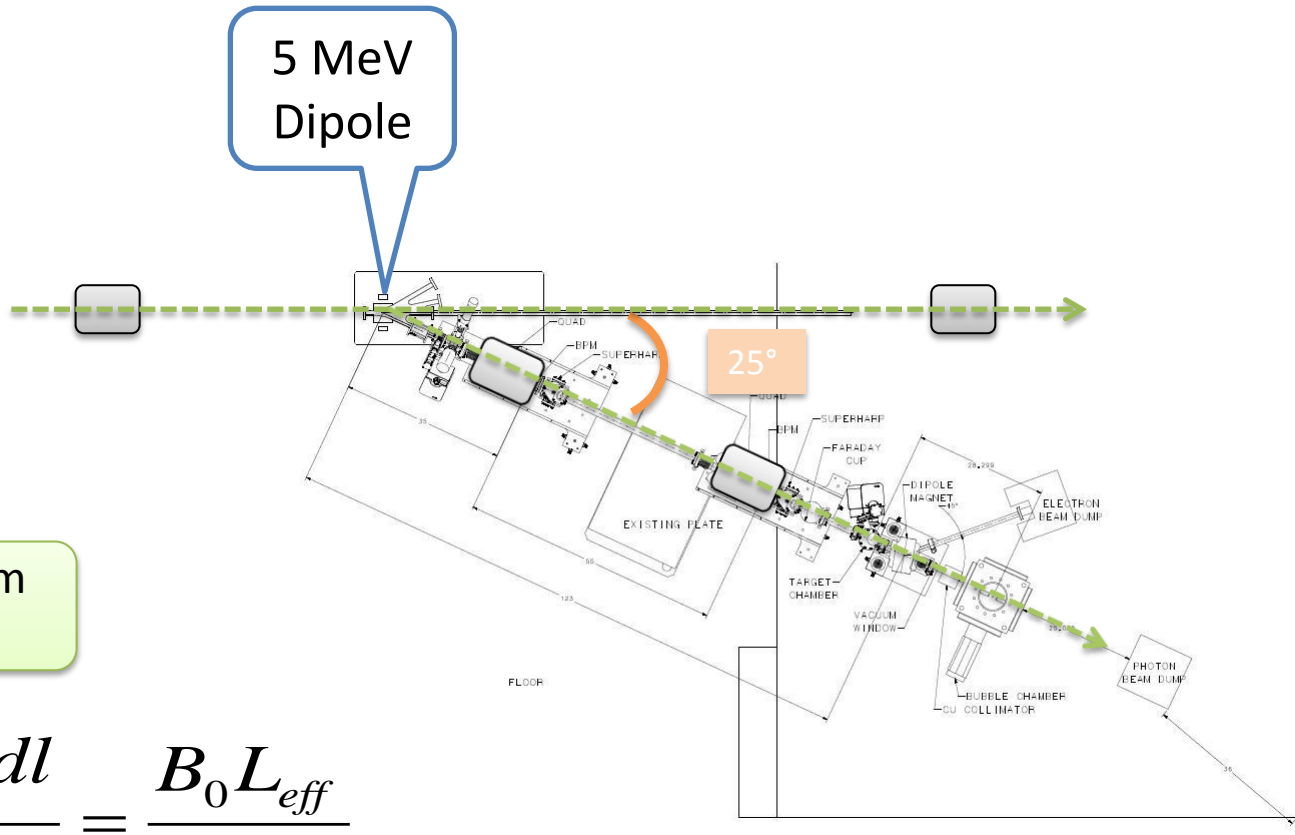

II. PEPPo achieved  $p=8.25$  MeV/c or K.E.=7.75 MeV. Maximum stable  $\frac{1}{4}$ - cryounit cavity gradients achieved: 8.4 MV/m and 6.1 MV/m (7.25 MV/m average). Vacuum in the beam line indicates that field emission and desorbed gas are the most problematic, but improve with processing.

III. Helium process the  $\frac{1}{4}$ -cryounit

# ABSOLUTE BEAM ENERGY

□ BPM

5 MeV Dipole

Electron Beam Momentum

$$p = \frac{\int B dl}{\theta} = \frac{B_0 L_{eff}}{\theta}$$

## ➤ Absolute beam energy is now known to 1%:

New larger dipole magnet with better field uniformity

- New and very accurate field map
- Build a detailed TOSCA model
- Add a Hall probe or NMR magnetometer for field monitoring
- Accurate and more stable power supply
- Add mu metal on all beam pipes to shield Earth field

## ➤ For 8.5 MeV/c: dipole current = 3.3 A, $B_0 = 1120$ G

### ➤ Error Budget:

– Bending angle:

$(\Delta\theta/\theta) \sim \text{BPM Resolution} / \text{distance between BPMs on PEPPo line} = 0.5\%$

– Field uniformity (variation in B across aperture):  $\Delta B/B_0 = 0.5\%$

– Effective Length:  $\Delta L_{\text{eff}}/L_{\text{eff}} = 0.13\%$

– Power supply:  $\Delta I/I = 2 \text{ mA} / 3.3 \text{ A} = 0.06\%$

– Earth field:  $0.5 \text{ G} / 1116 \text{ G} = 0.04\%$

# Non-resonant charged particle reactions (The Gamow peak)

Let's write the cross section as  $\sigma(E) = \frac{1}{E} \exp(-2\pi\eta) S(E)$

and substitute in  $\langle \sigma v \rangle = \left(\frac{8}{\pi\mu}\right)^{1/2} \frac{1}{(kT)^{3/2}} \int_0^\infty \sigma(E) E \exp\left(-\frac{E}{kT}\right) dE$

If no resonances are present  $S(E) = S(E_0) = \text{constant}$ , so

$$\langle \sigma v \rangle = \left(\frac{8}{\pi\mu}\right)^{1/2} \frac{1}{(kT)^{3/2}} S(E_0) \int_0^\infty \exp\left(-\frac{E}{kT} - \frac{b}{E^{1/2}}\right) dE \quad b = \left(\frac{2\mu}{\hbar^2}\right)^{1/2} \pi Z_1 Z_2 e^2$$

## Gamow peak

- \* The rate has a peak shape product of two negative exponentials: Maxwell-Boltzmann distribution at low energy and tunneling through the Coulomb barrier for higher E.
- \* It represents the region in energy where reactions are more likely to occur.
- \* The concept can be extended to a general  $S(E)$

- Measure Yields at:  $E = E_1, E_2, \dots, E_n$  where,

$$E_i - E_{i-1} = \Delta, i = 2, n$$

$$Y(E_i) = \int_{th}^{E_i} n_\gamma(E_i, k) \sigma(k) dk \approx \sum_{j=1}^i N_\gamma(E_i, \Delta, E_j) \sigma(E_j)$$

- The solution can be written in two forms:

$$\sigma_i = \frac{1}{N_{ii}} \left[ y_i - \sum_{j=1}^{i-1} (N_{ij} \sigma_j) \right]$$

- Or, Matrix form:

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} N_{\gamma,11} & 0 & \dots & 0 \\ N_{\gamma,21} & N_{\gamma,22} & \dots & 0 \\ \vdots & \ddots & \ddots & 0 \\ N_{\gamma,n1} & N_{\gamma,n2} & \dots & N_{\gamma,nn} \end{bmatrix} \begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \vdots \\ \sigma_n \end{bmatrix}$$

# SAFETY

## ➤ Super heated liquid N<sub>2</sub>O, Nitrous oxide (laughing gas)

- I. At room temperature, it is a colorless, non-flammable gas, with a slightly sweet odor and taste

## ➤ High pressure system:

- I. Design Authority: Dave Meekins
- II. T=
- III. P=

## ➤ Buffer liquid: Mercury

- I. Closed system
- II. Volume: 135 mL
