

Implementing the laser profile \* QE scan profile  
as a one image into GPT

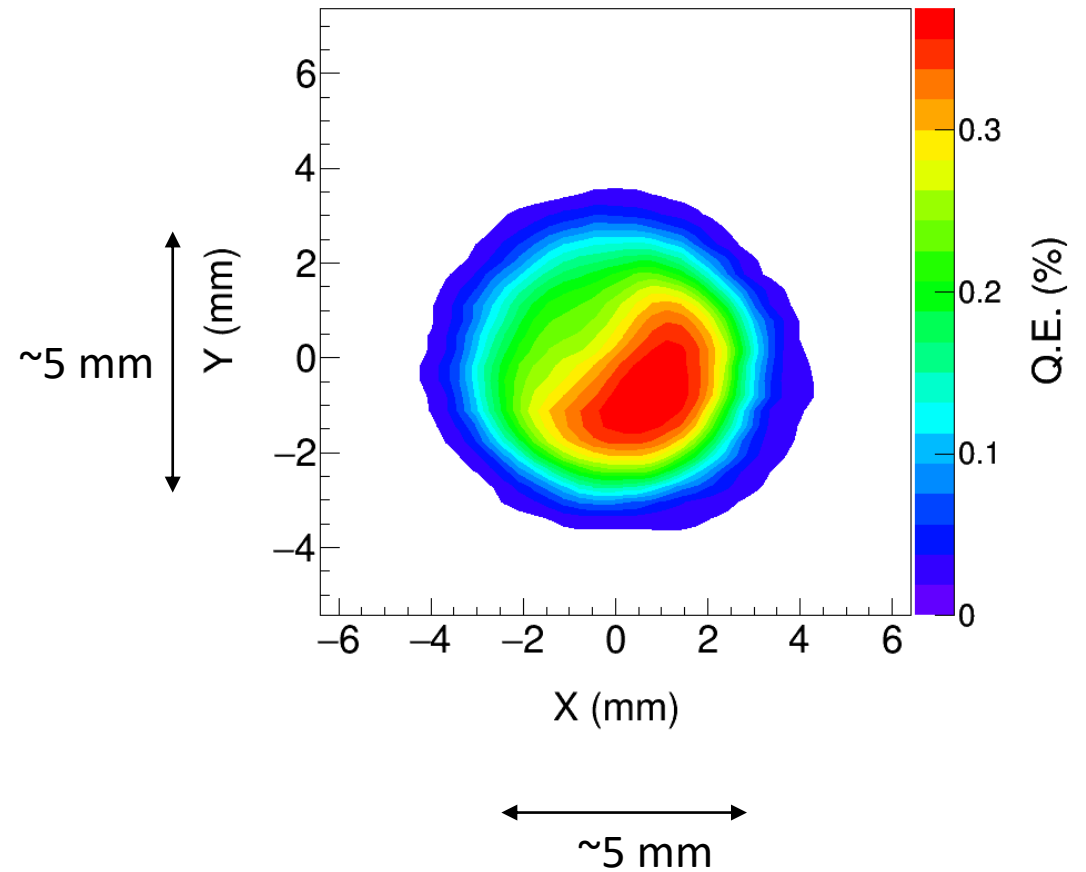

07/24/2019

Laser profile for  $\sigma = 1.64$  mm

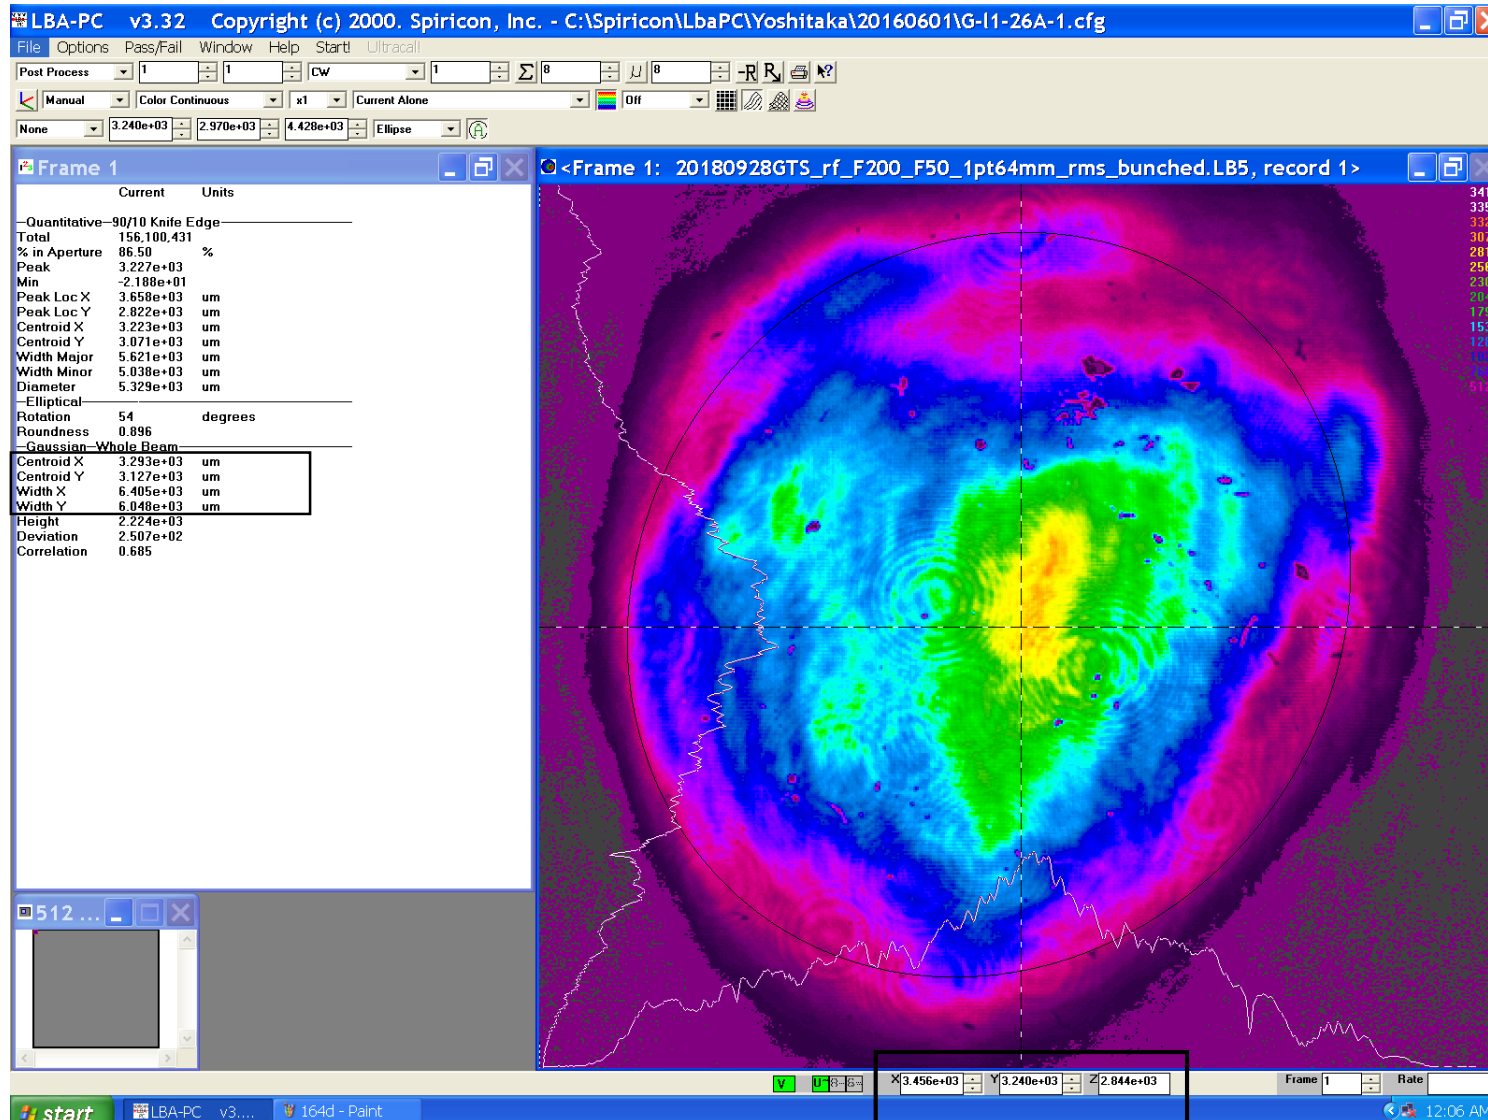

1 px=0.01347 mm

QE scan of the 90 min Sb photocathode  
(Full active area)

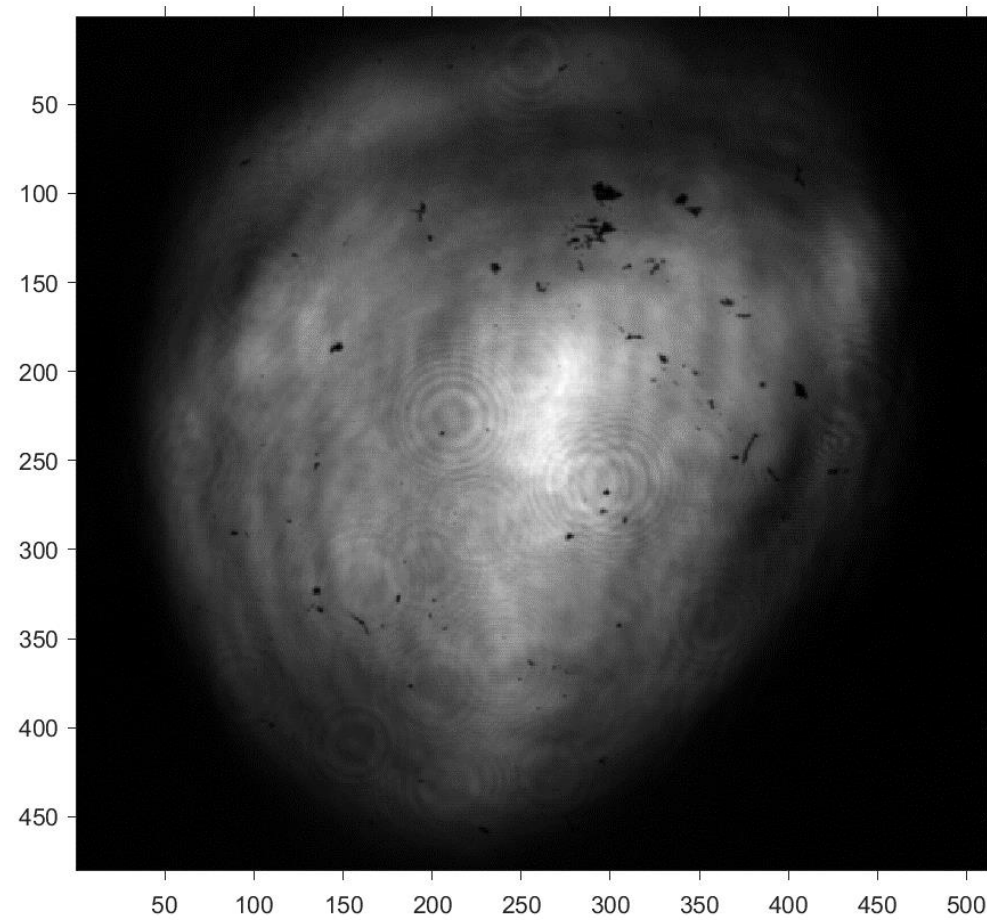

- In order to use an image as the initial particle distribution in GPT it has to be grayscale, 8-bit per pixel .bmp file.
- Image details shows in the Spiricon software:

## Steps

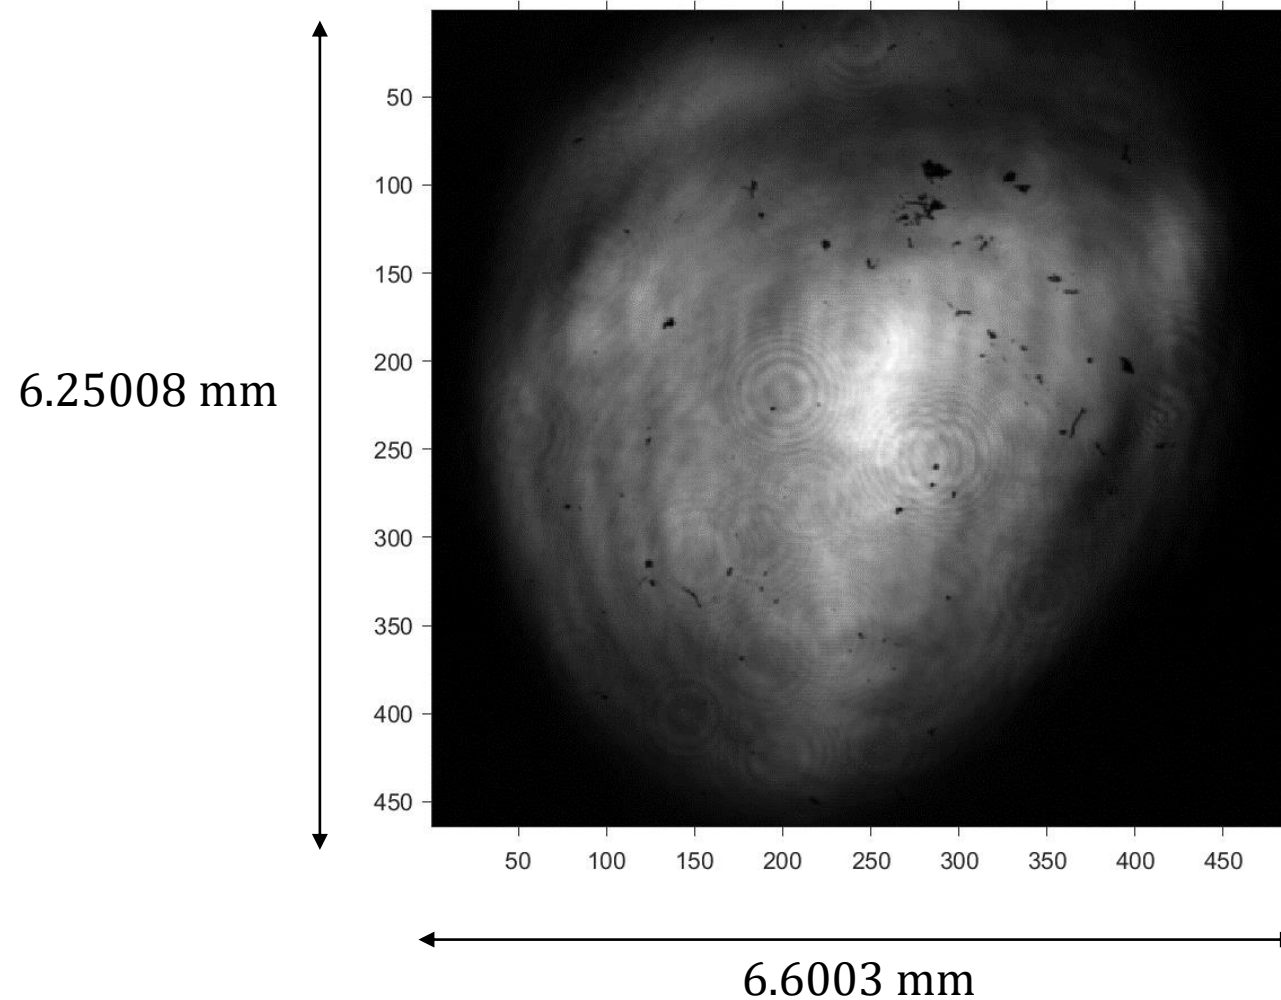

- Get the .cma file from Spiricon software, which is a 480\*512 matrix.
- Convert it into a grayscale image (converts the matrix to an intensity image that contains values in the range 0 (black) to 1 (white)).

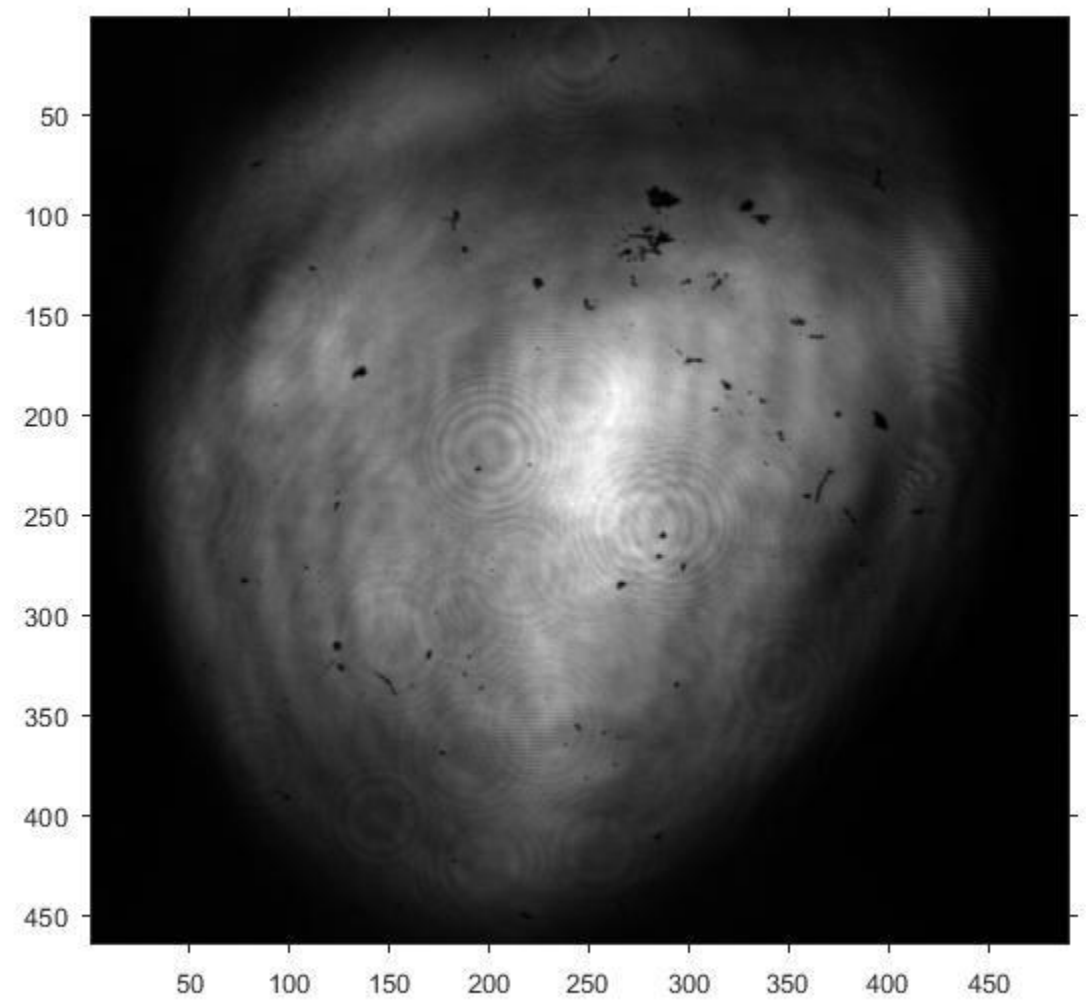

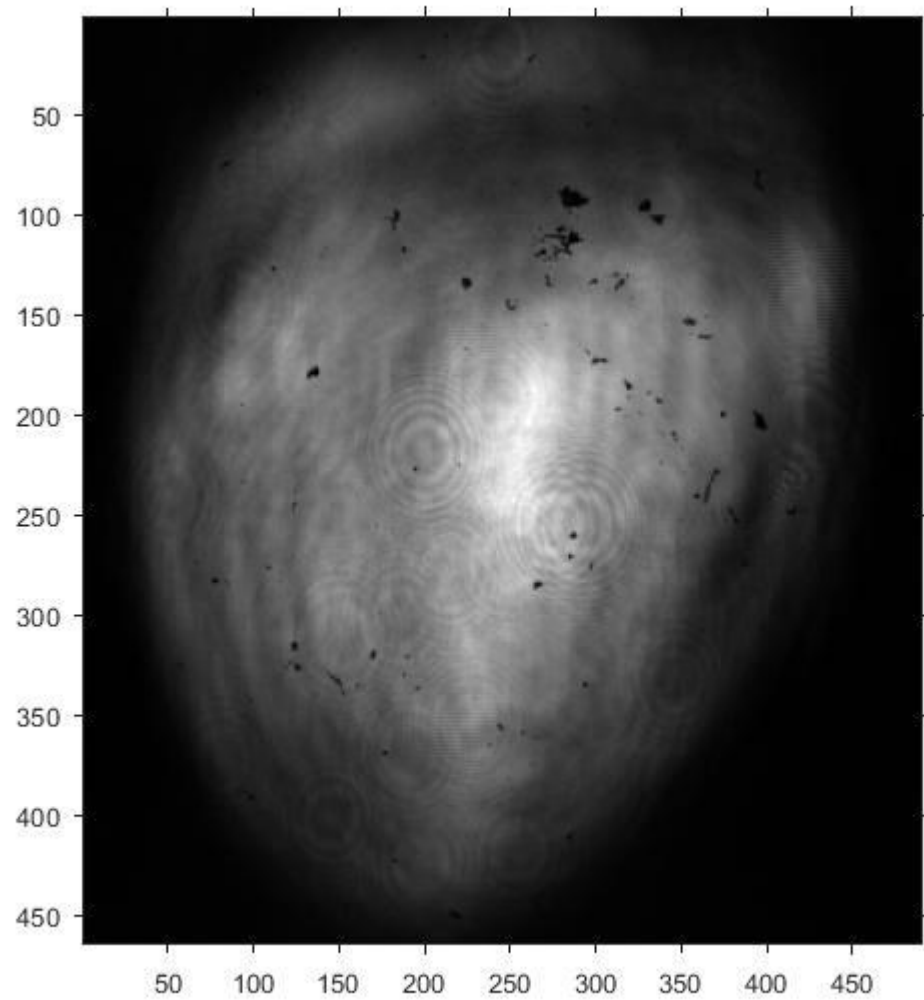

- Crop the image such that the center of the image is the center of the laser spot.

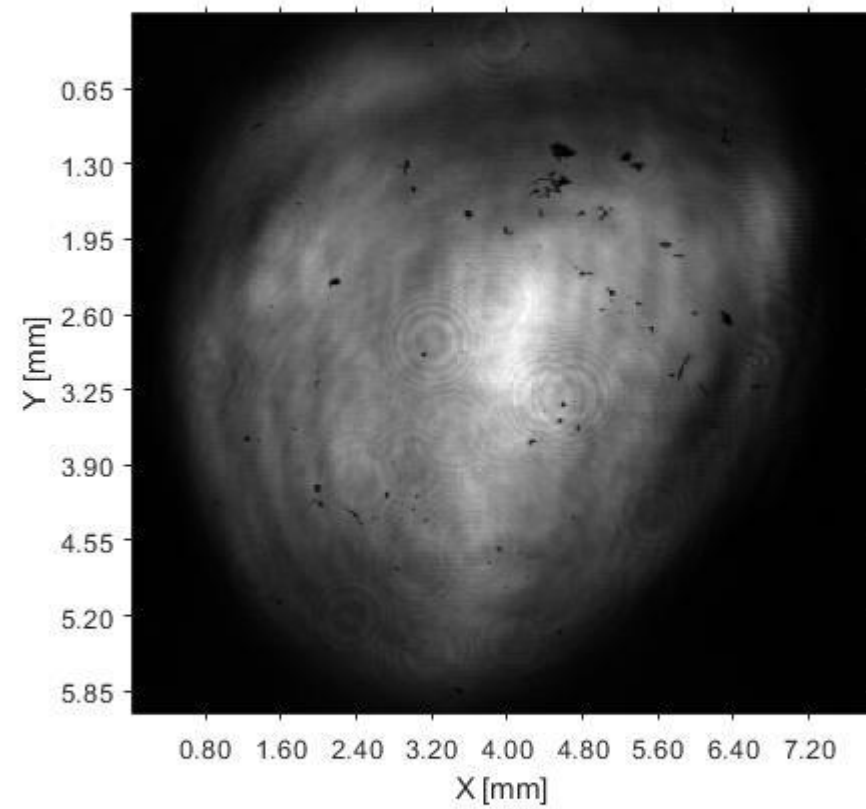

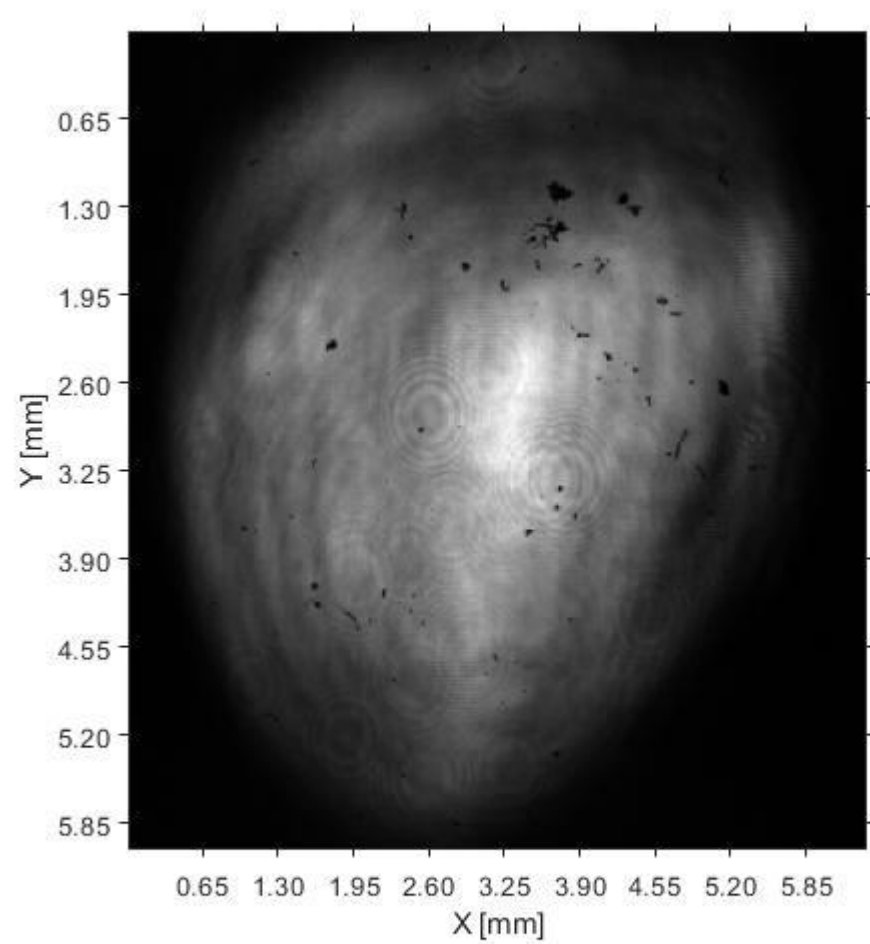

Centroid coordinates X= 3.293 mm, Y=3.127 mm

$\frac{1}{e^2}$  X = 6.405 mm, Y = 6.048 mm

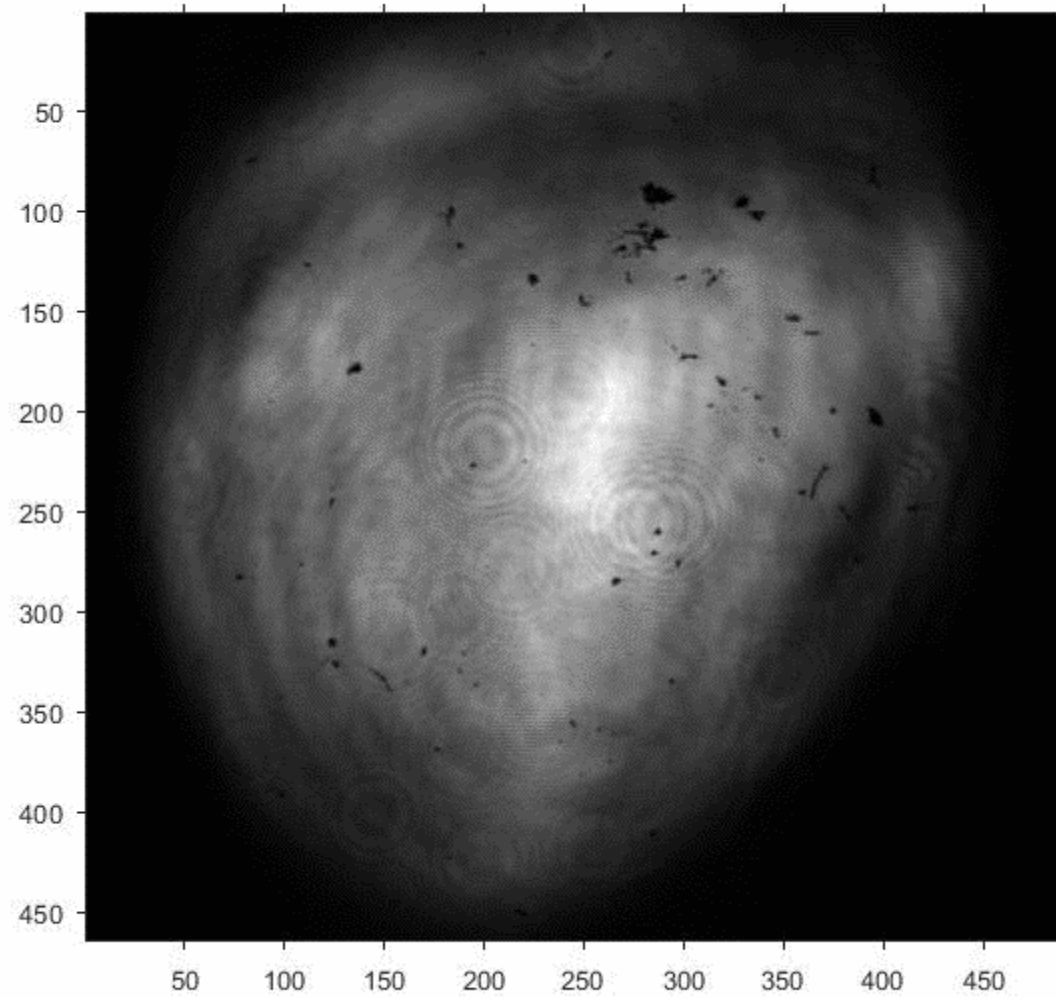

- Since the laser hit the cathode at 25 degree angle, updated the aspect ratio of the image.  $\frac{x}{y} = 1.1690$

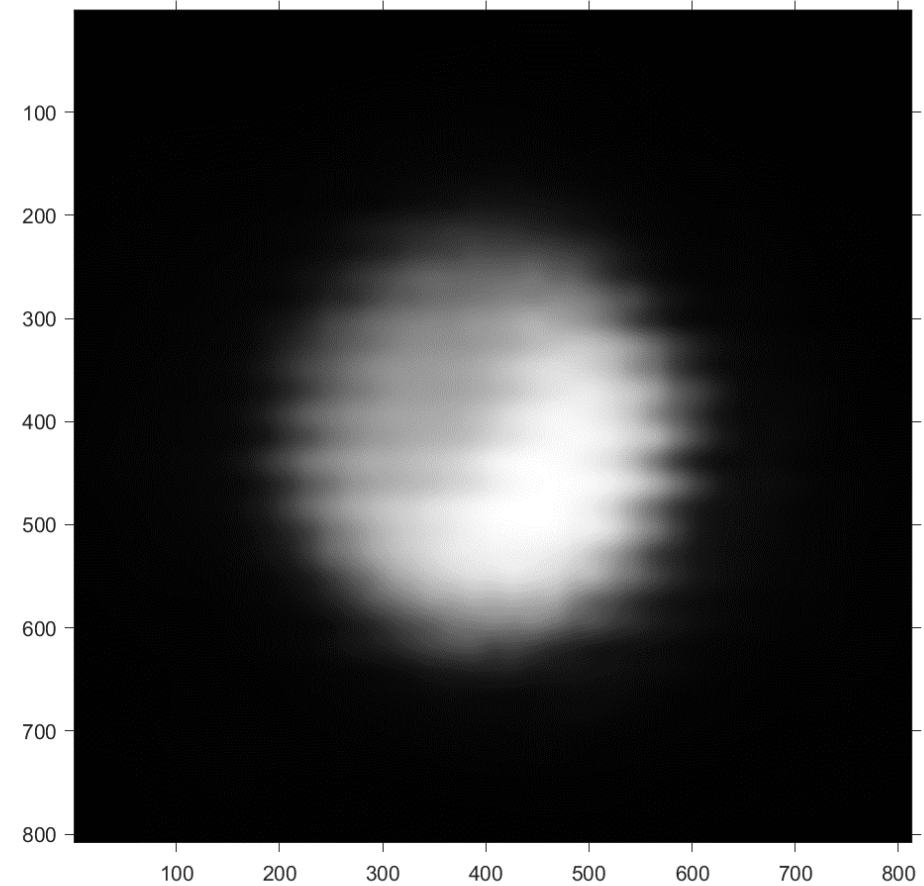

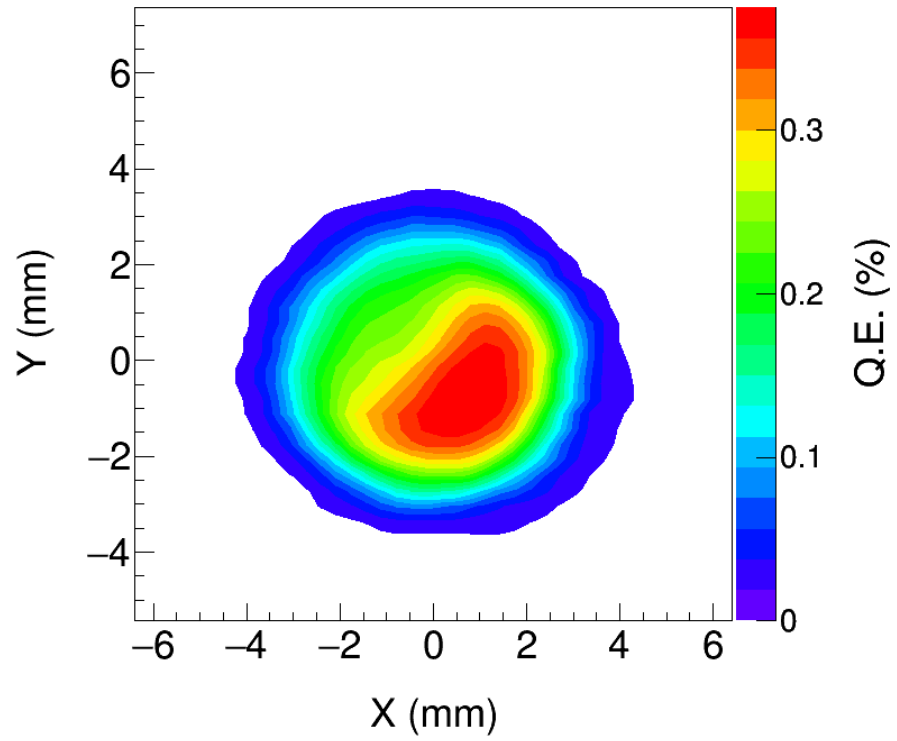

- Convert the 24 bit image to 8 bit image.

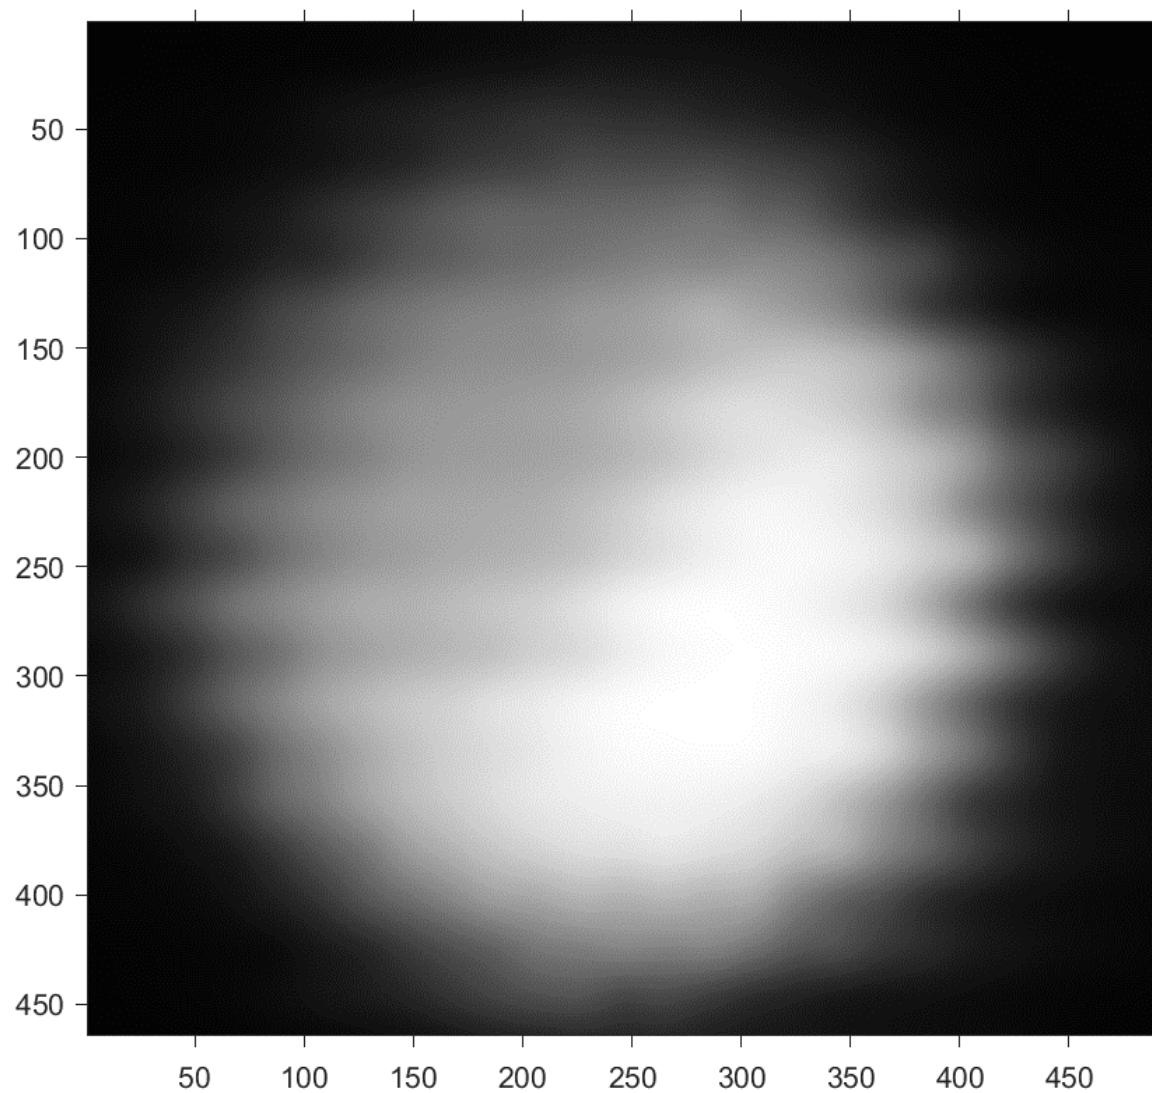

## QE scan image

### Steps

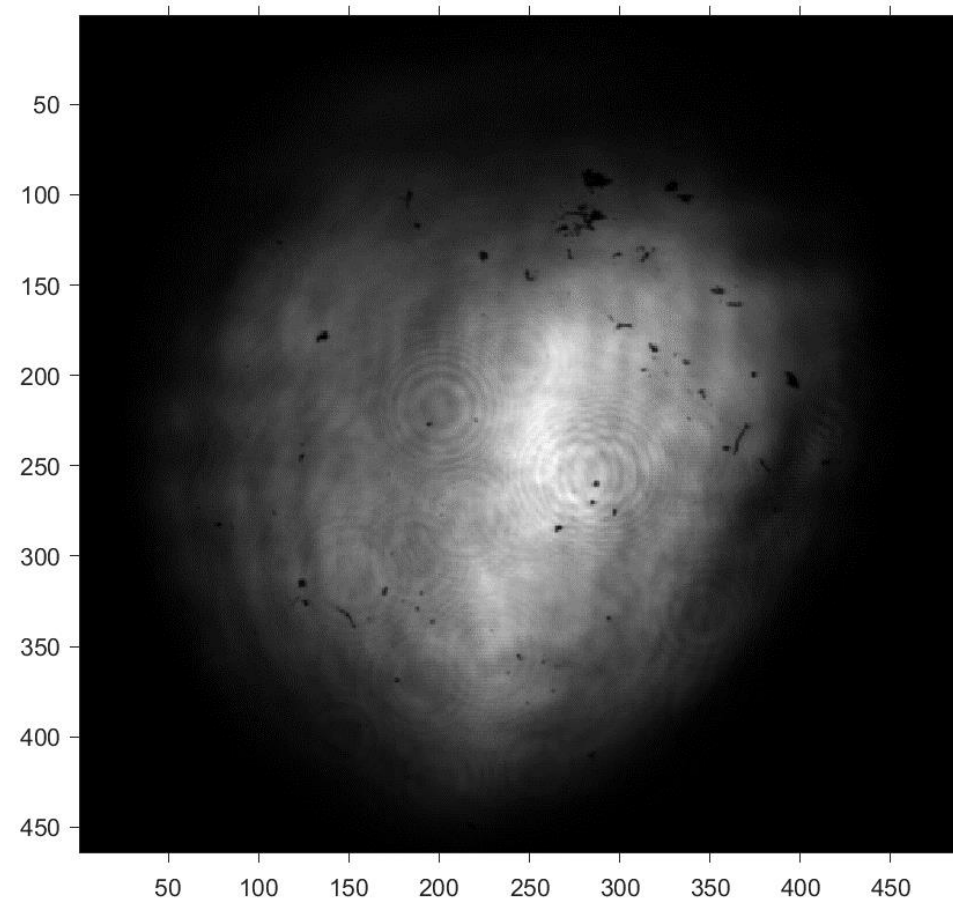

- Get the matrix of the QE profile and make the center of the active area the center of the QE image.
- Normalized to 1.

- Scale it to match the px/m ratio of the laser image.
- Crop the QE image to the size of the laser image.

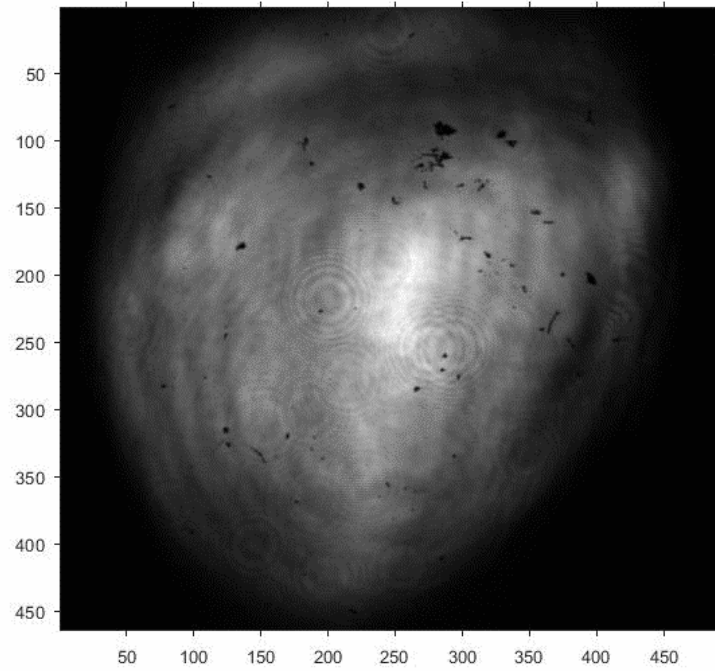

- Multiply the to matrix (laser image\*QE).
- Normalized to 1.

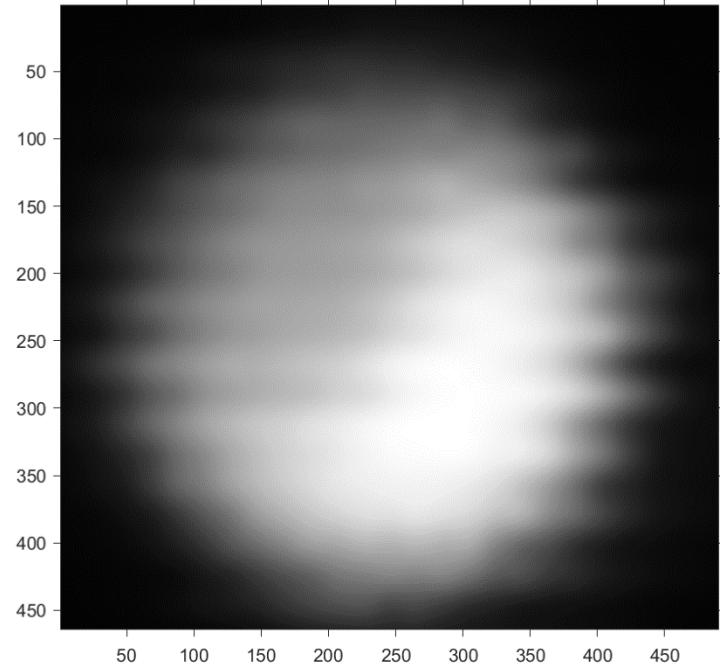

- Convert the 24 bit image to 8 bit image.

# Summary

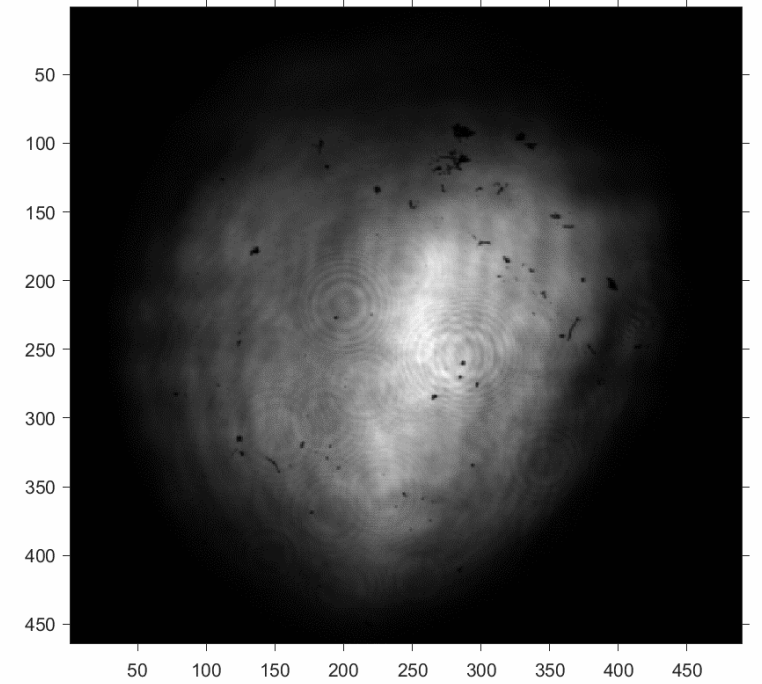

Laser profile

QE scan

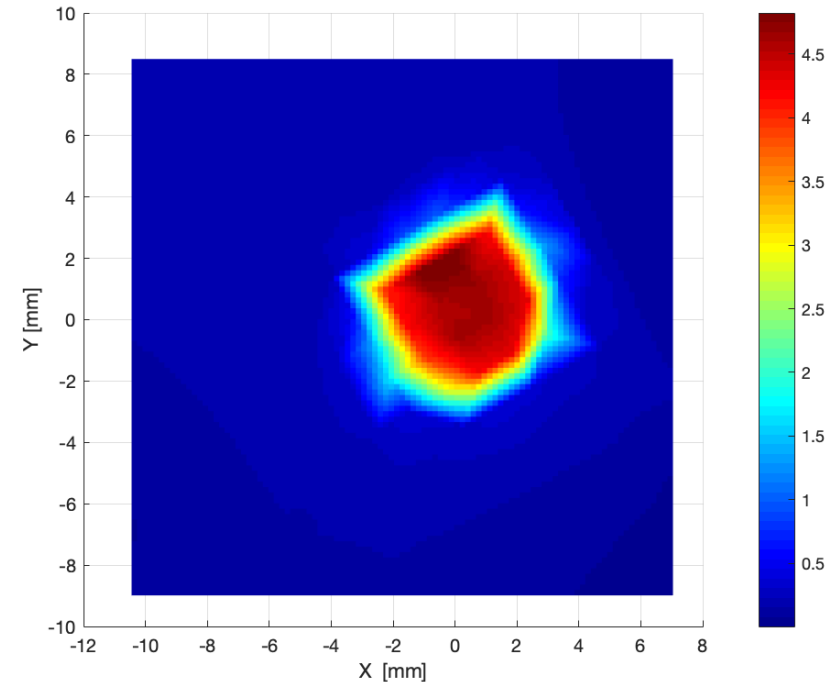

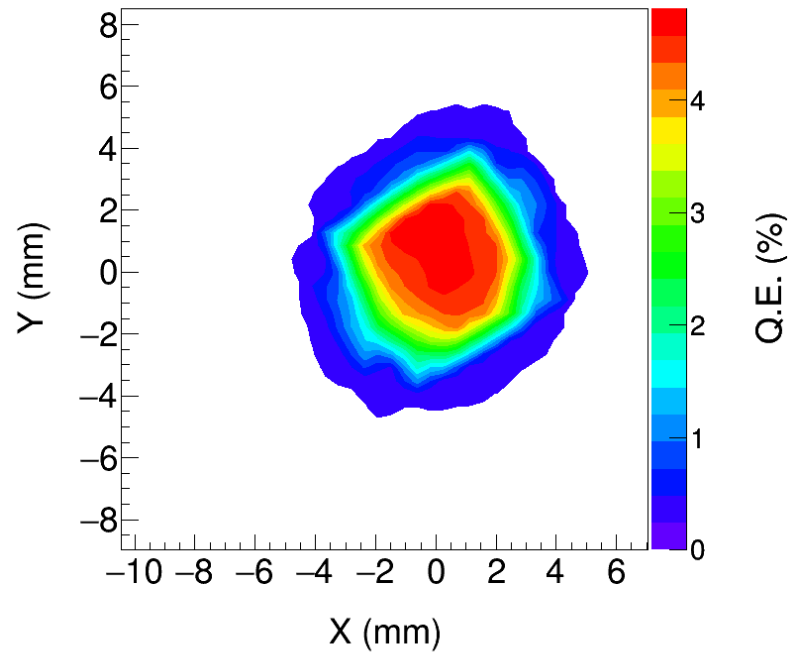

Laser\*QE

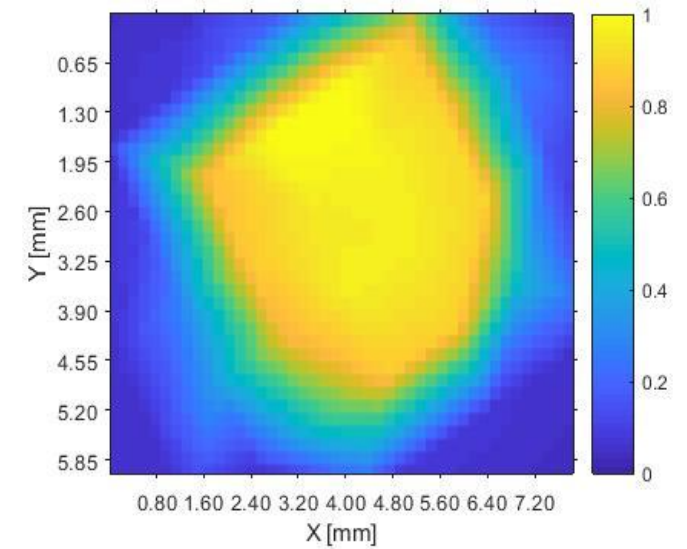

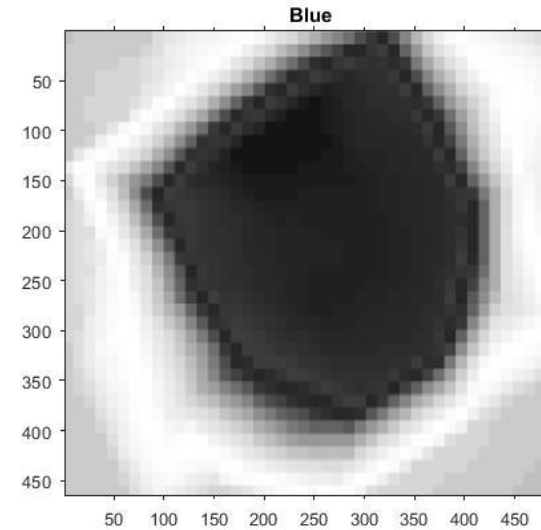

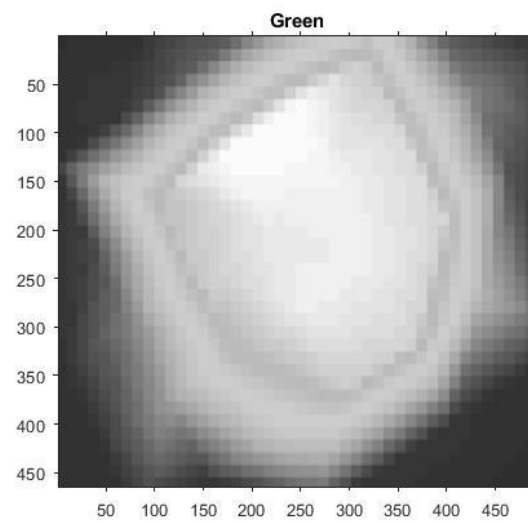

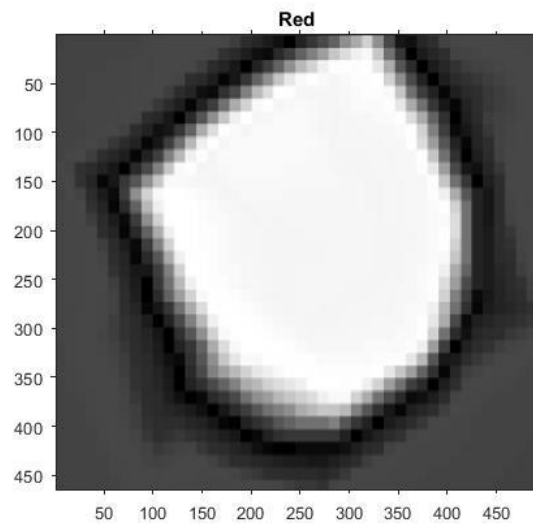

## QE scan did in June'18 for 90 min Sb photocathode

- Plot the original scan data from the .sdds file in X Y coordinates by making the center (0,0) and save that data file in .txt format.
- Make a surface plot from the .txt file (as the step size of the rotated data is large and not a constant, have to do interpolation)
- Save that surface plot as image and convert it to a matrix.

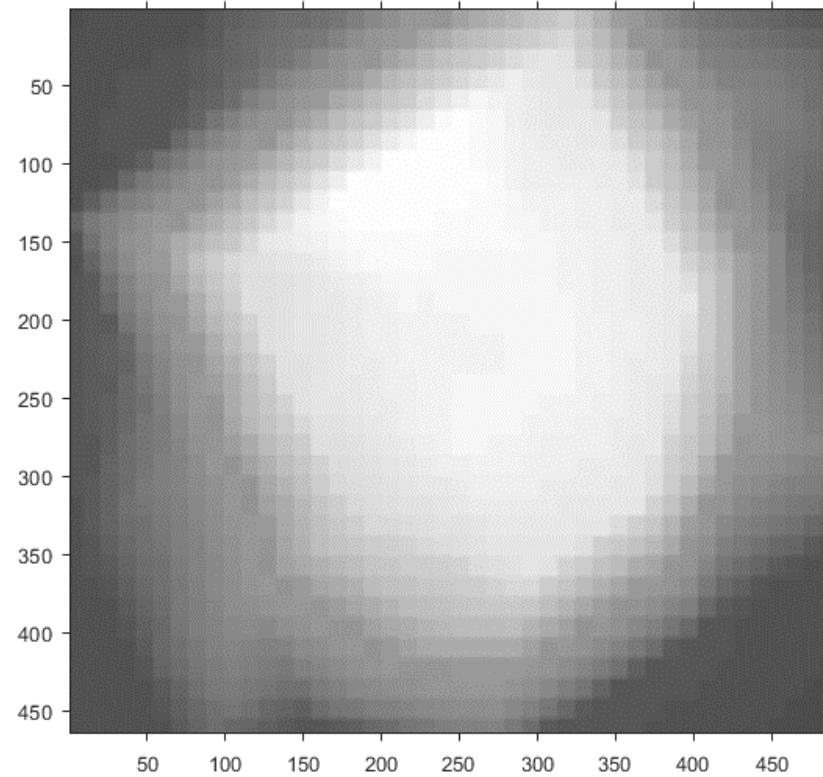

- Matrix comes out as a RGB matrices (3 matrices) which by concatenating the 3<sup>rd</sup> degree gives the original image.
- Therefore do the further calculations separately for the 3 matrices and finally concatenate them.

- Cropped the image such that the center of the image is the center of the QE scan.
- Scale it to match the px/m ratio of the laser image.
- Crop the QE image to the size of the laser image.

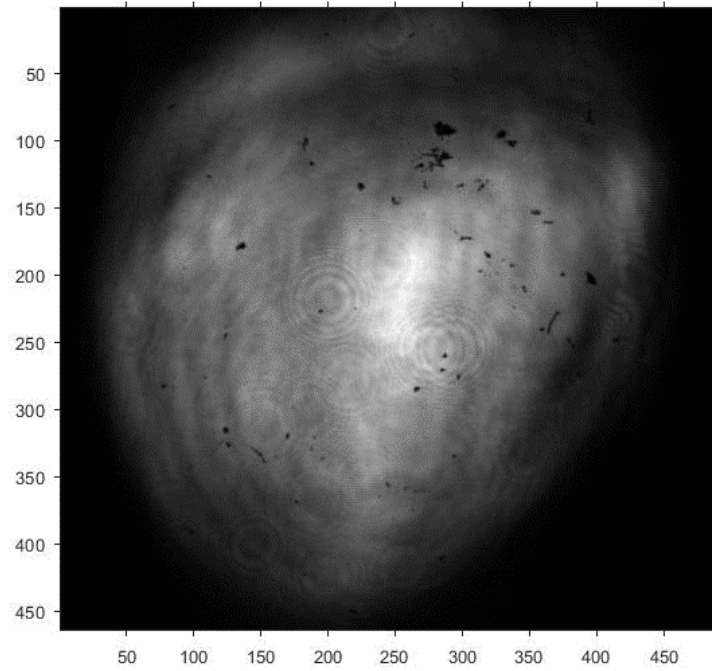

- Convert to a gray scale image.
- Normalize.

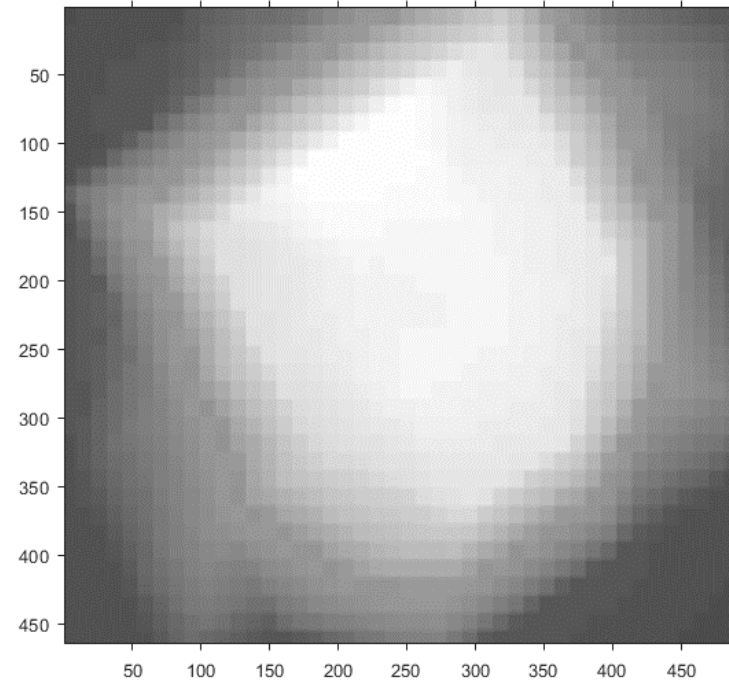

- Multiply the two matrices (Laser \* QE)
- Normalize.
- Convert 24 bit to 8 bit image.

# Summary

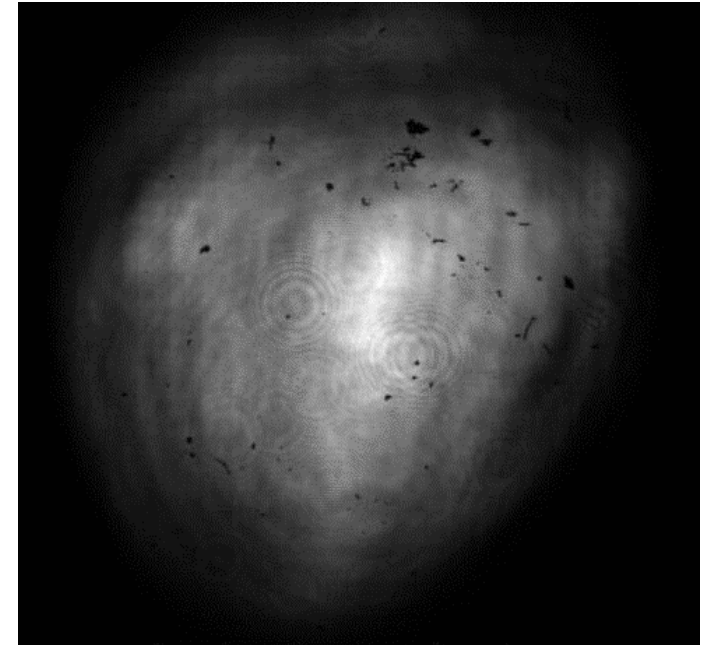

Laser profile

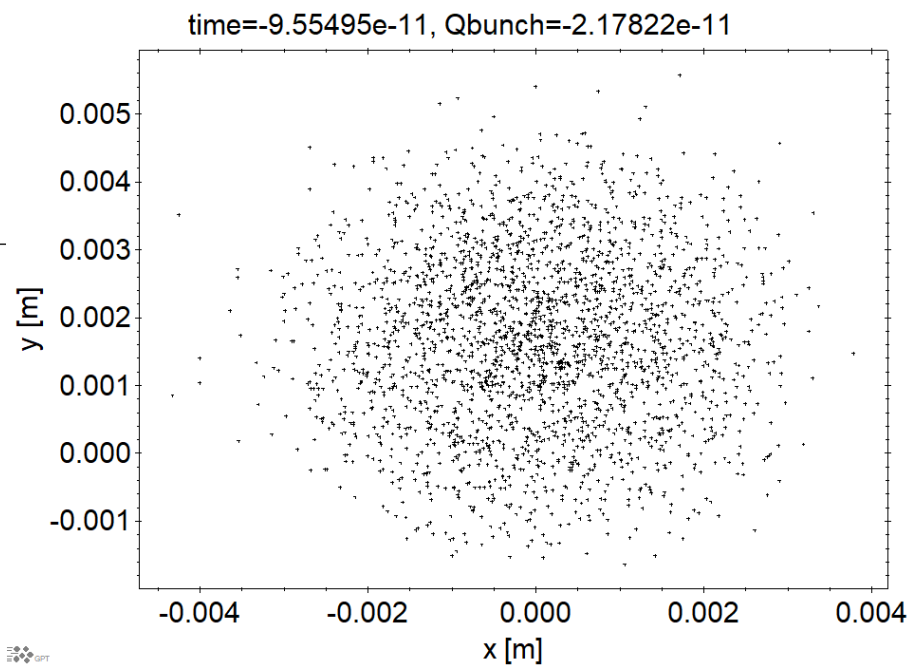

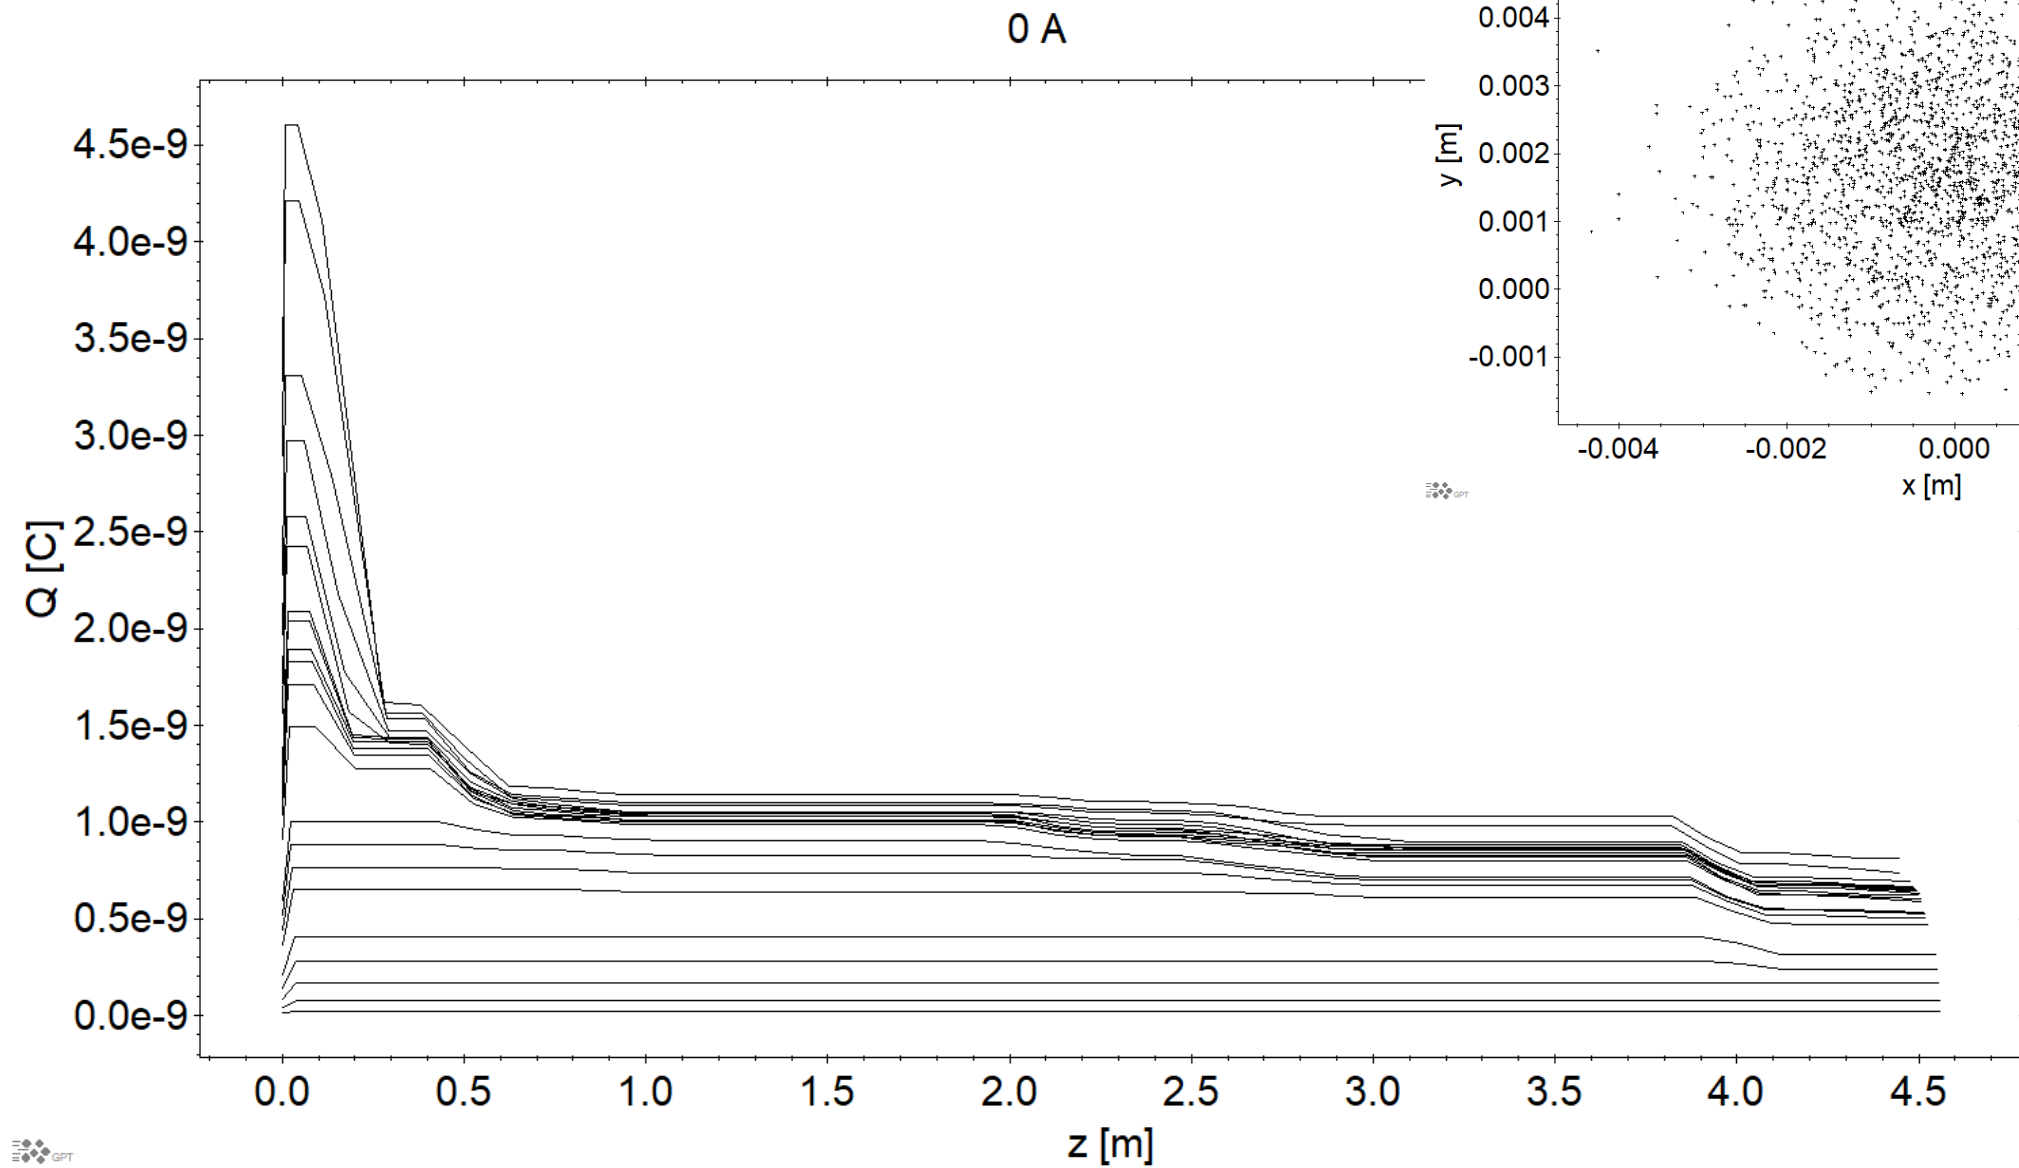

QE scan

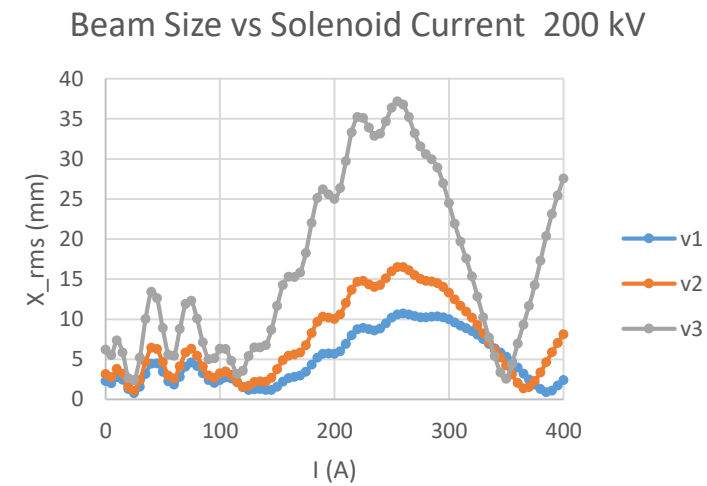

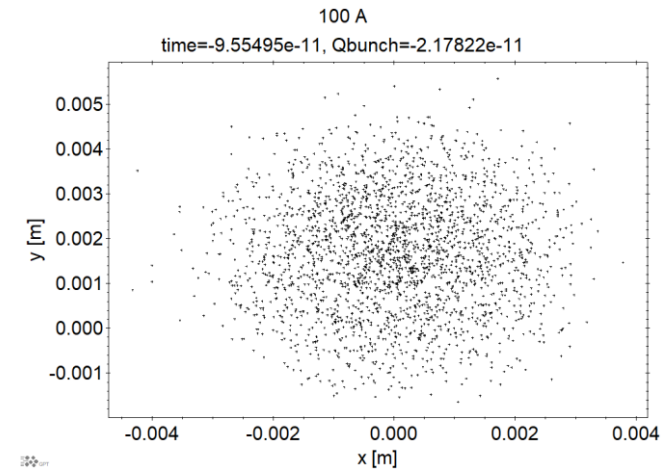

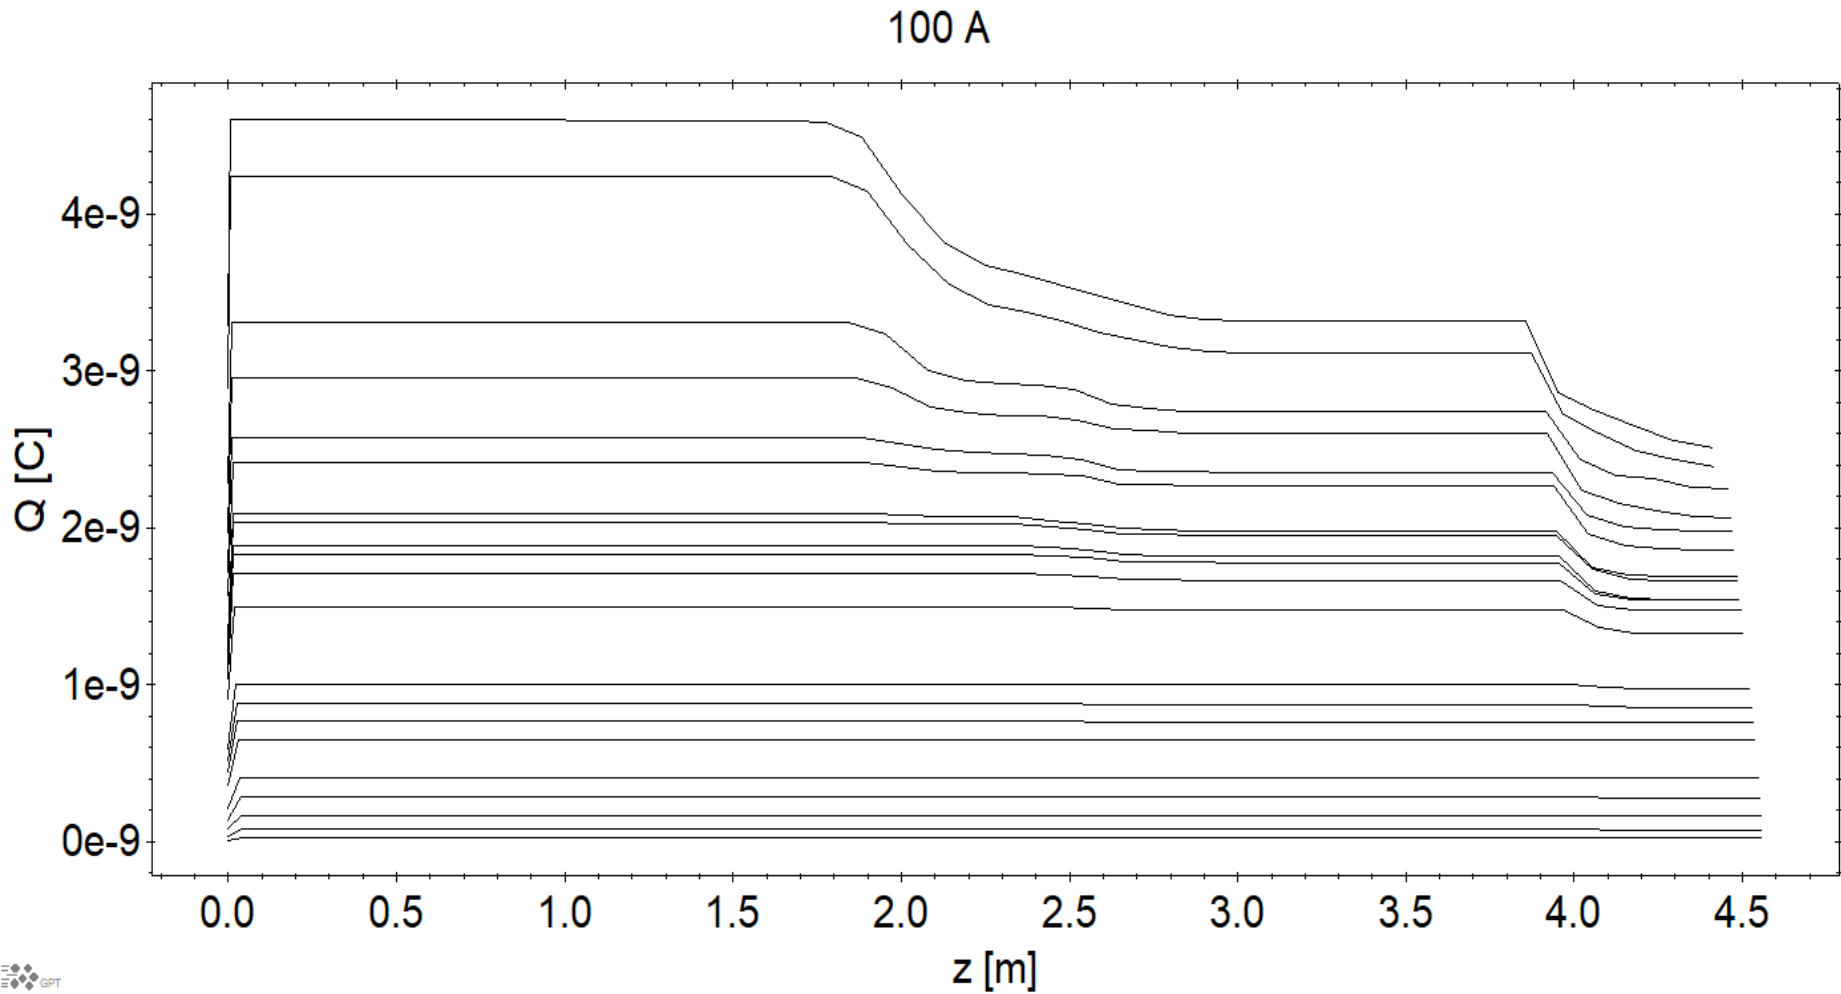

Laser\*QE

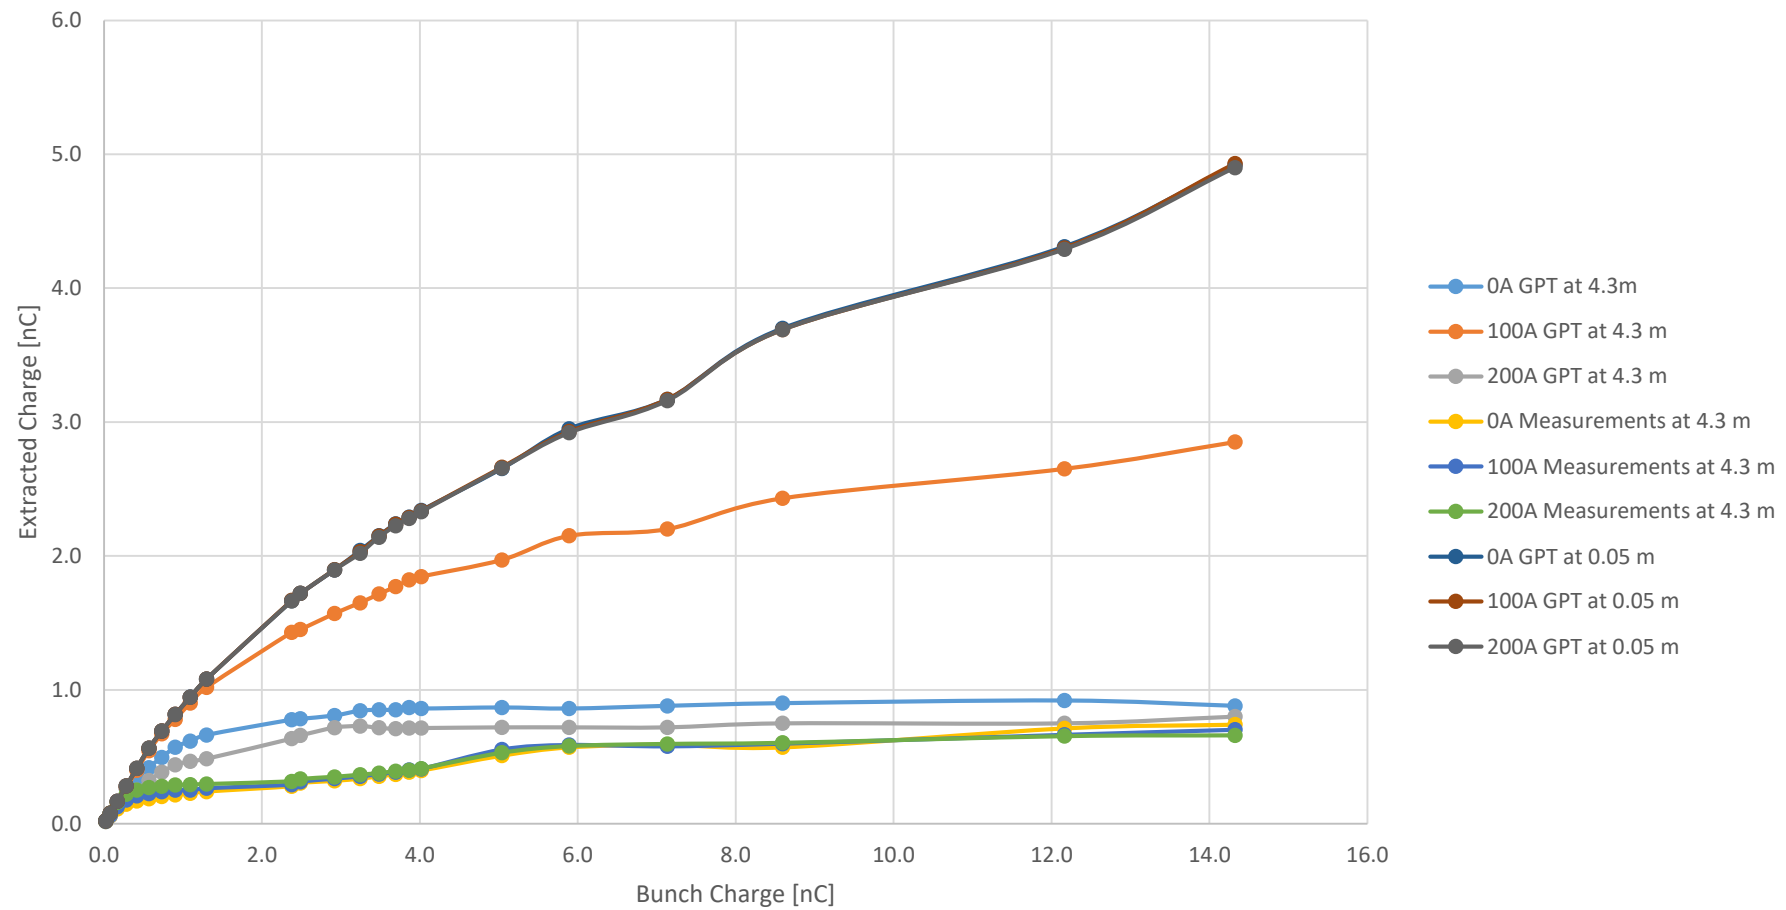

0 A

# 100 A

Extracted Charge vs input charge for 0 A, 100 A, 200 A  
225 kV, 50 kHz, 1.64 mm rms, 75 ps (FWHM)

Extracted Charge vs input charge for 0 A, 100 A, 200 A  
225 kV, 50 kHz, 1.64 mm rms, 75 ps (FWHM)
