

Target Energy Loss Study with SIMC
Bishnu Pandey
March 23, 2022

In this study the same target and kinematics is used as used in the E12-17-003 Experiment

Target Parameters Used:

Target wall thickness = 400 μm

Target Length = 25 cm

Target diameter = 12.7 mm

Target thickness = 84.8 mg/cm^2

Kinematics Used:

Beam energy = 4326.0 MeV

Electron arm central momentum = 2218.0 MeV/c

Electron arm angle = 13.2 $^\circ$

Hadron arm central momentum = 1823.0 MeV/c

Hadron arm angle = 13.2 $^\circ$

Electron arm = HMS

Hadron arm = SHMS

Energy Loss for the Beam Electron:

SIMC doesn't have any leaf variable to calculate the energy loss for the beam electron when it passes through the Al window (target cell entrance window), so it can not be printed in a histogram. However, it can print the average energy loss as a number.

In this study, I ran 500 K events. The average energy loss when the electrons passes through the Al entrance window is as follows:

Lowest value = 0.15960 MeV

Highest value = 0.41815 MeV

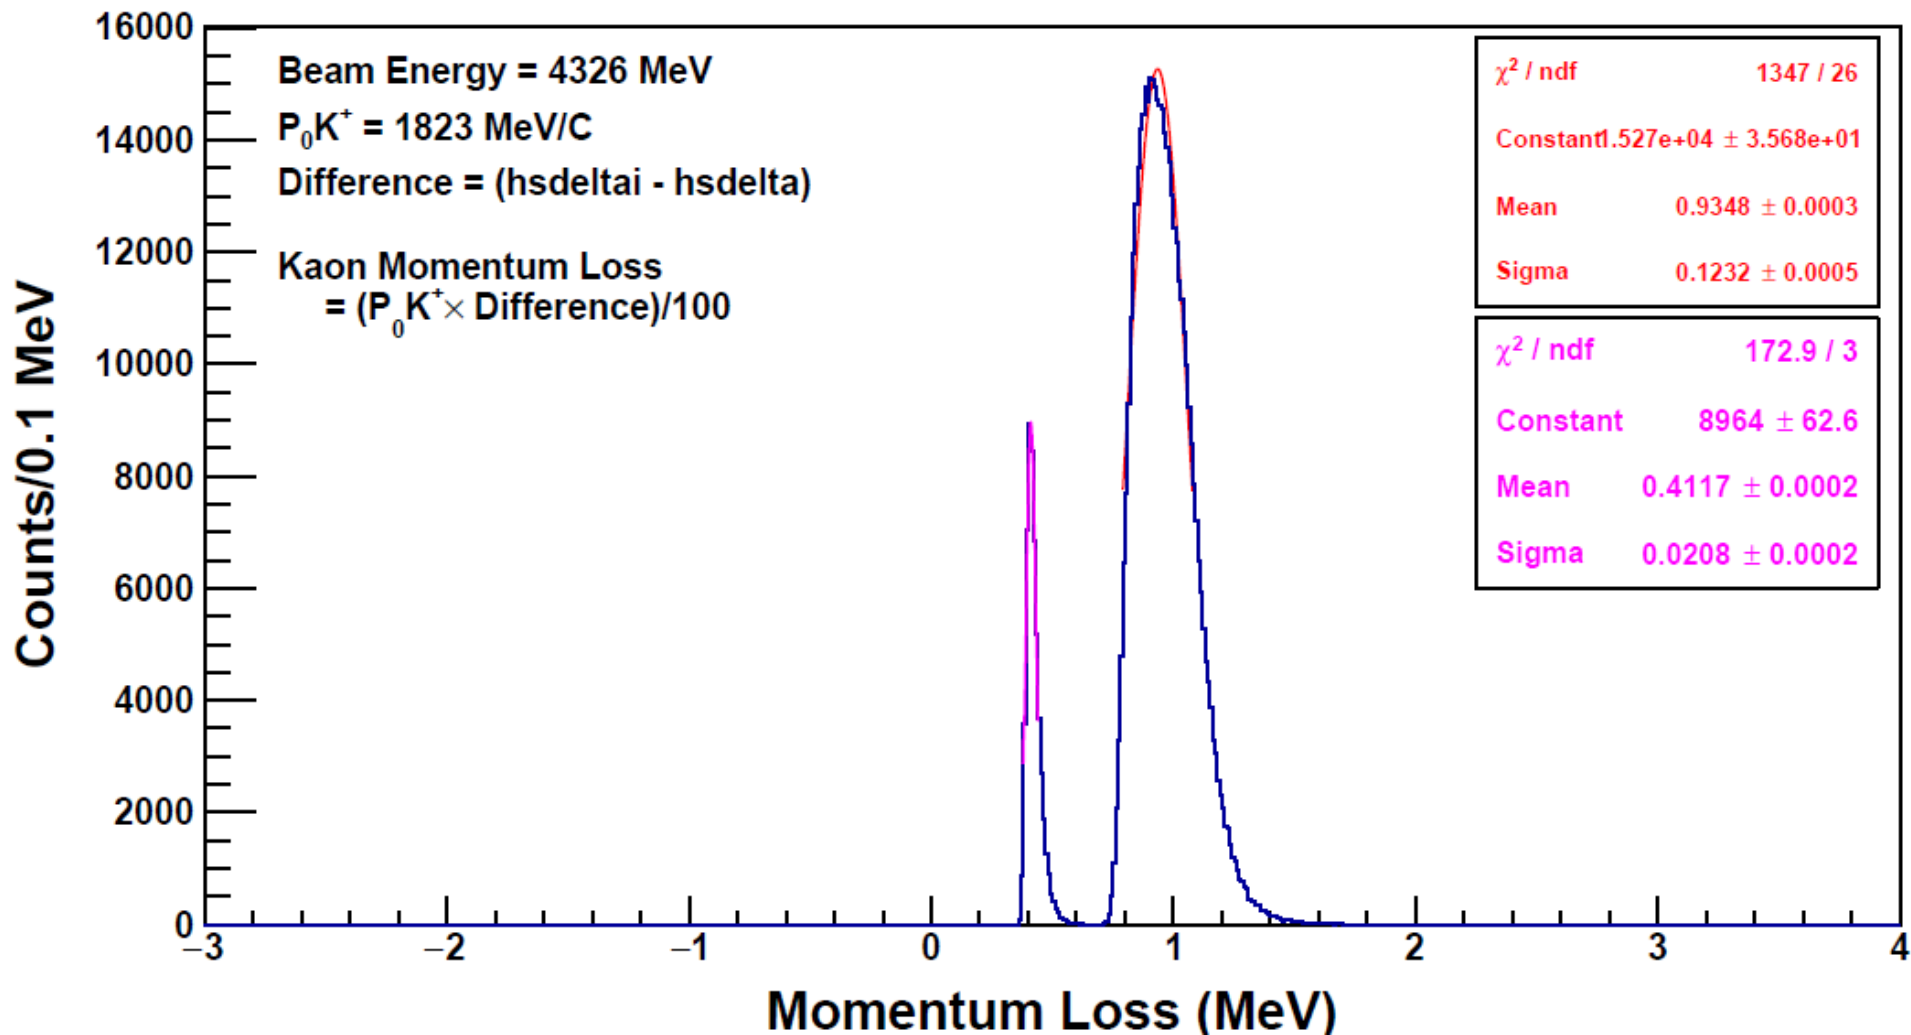

Average energy loss = 0.23443 MeV

Note: The average energy loss may be different if we run different number of events. For 500 K the average loss ~ 0.23 MeV.

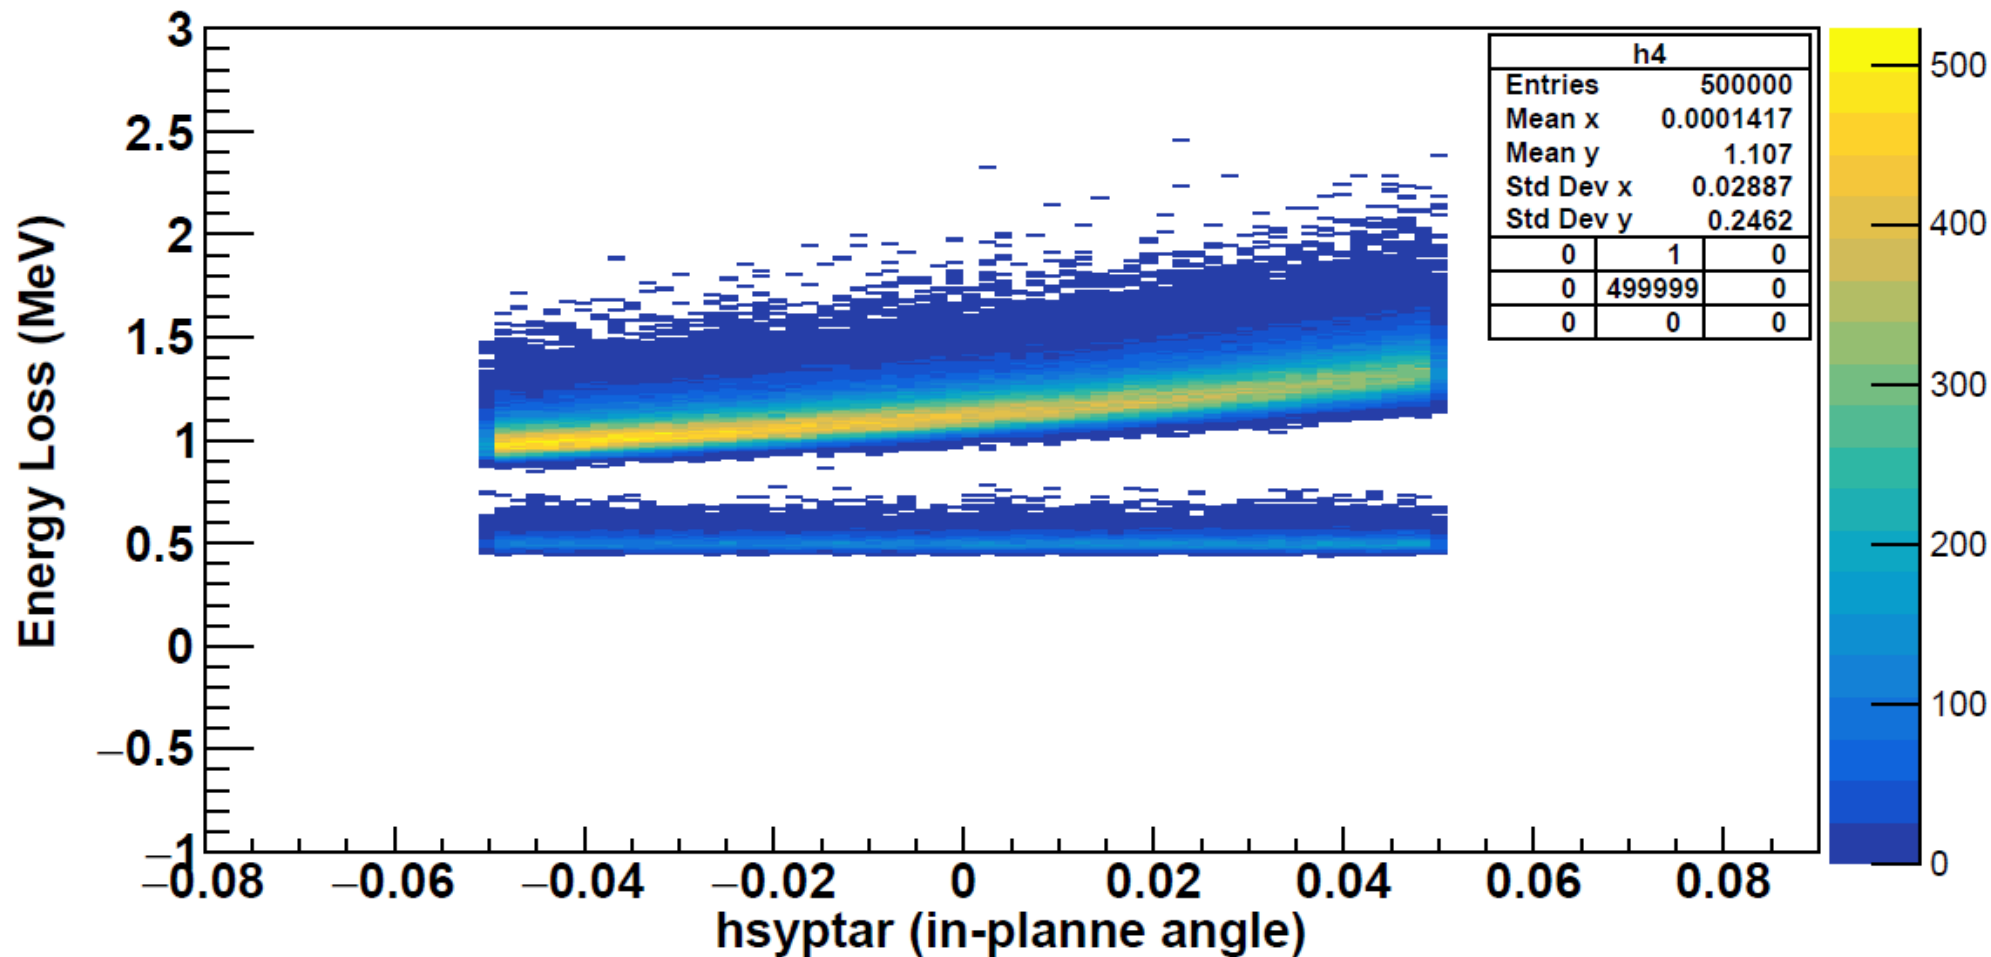

Scattered Electron Momentum Loss

Kaon Momentum Loss

Electron Energy Loss vs in-plane angle (hsyptar)

Kaon Energy Loss vs in-plane angle (hsyptar)
