

MARATHON Counting Rates Estimation

Sheren Alsalmi, Tyler Hague, Mike Nycz, Tong Su

October 31, 2017

Abstract

A preliminary calculation of counting rates for MARATHON is introduced in this report. So far, it is assumed -as told by Jessie- that the maximum angle for the LHRS is 38.5 with the tritium platform still connected. The maximum angle value should be confirmed in the following few weeks. For now, I checked the counting rates using the kinematics Makis suggested (Table.1). In Table.2, I tried to change the kinematics only for the highest x point at the maximum angle ,38.5, to reach $W^2 \sim 3.5$.

Input Values

- Target Densities:

$$\rho_{H3} = 0.00363 (\times 0.85)$$

$$\rho_{He3} = 0.00425 (\times 0.9)$$

$$\rho_{H2} = 0.00568 (\times 0.9)$$

The values between () are multiplied by the densities due to beam-heating effects.

- HRS Acceptance:

Energy acceptance: $|\delta E'| < 4.5\%$

Angle acceptance: $|\theta_{tg}| < 0.045$ rad, $|\phi_{tg}| < 0.032$ rad.

The total angular acceptance range for both HRS's is:

$$2 \times (2 \times 0.045) \times (2 \times 0.032) \approx 0.01 \text{ sr}$$

- Target Length: The full target length is 25 cm. However, an approximate effective length (12 cm) is used in this calculation.

- Beam current:

$$I = 20 \mu A$$

- Target Luminosities:

$$Lum_{H3} = 0.93 \times 10^{36} \text{ cm}^{-2} \cdot s^{-1}$$

$$Lum_{He3} = 1.15 \times 10^{36} \text{ cm}^{-2} \cdot s^{-1}$$

$$Lum_{H2} = 2.31 \times 10^{36} \text{ cm}^{-2} \cdot s^{-1}$$

- For the rate estimation, the number of events needed for each x point is assumed to be 25k
- For each kinematic point, π/e ratio was calculated using Wiser fitting.
- For the cross section calculation, Whitlow's fit (Phys. Lett. **B282**, 475 (1995)) was used.
- Radiative effect and isoscaler correction were not applied in this calculation (yet!)
