

Previous issues: Small offsets in ytar and ztar

- Roughly $z_{tar} = y_{tar} / \sin(\theta)$
 - If z_{tar} matches close so should y_{tar}

$$Z_{react} = -Y_{coeff} \times aa_1 - X_{beam, recon} \times aa_2$$

$$\begin{cases} aa_1 = \frac{\cos(\arg 1)}{\sin(\arg 1 + \sin \theta_{spec} \theta_0)} \\ aa_2 = \cot(\arg 1 + \sin \theta_{spec} \theta_0) \end{cases}$$

$$Y_{coeff} = Y_{tar} + D - Z_{off} (\phi_{tar} - \phi_{off})$$

$$\arg 1 = \arctan(\phi_{tar} - \phi_{off})$$

$$X_{beam, recon} = \text{target \%} \times \text{offset} + \text{main \% target \% raster} \times$$

Thanks to Shujie! Found bug inside the event generator missing a contributing offset in the reconstruction of Ztar.

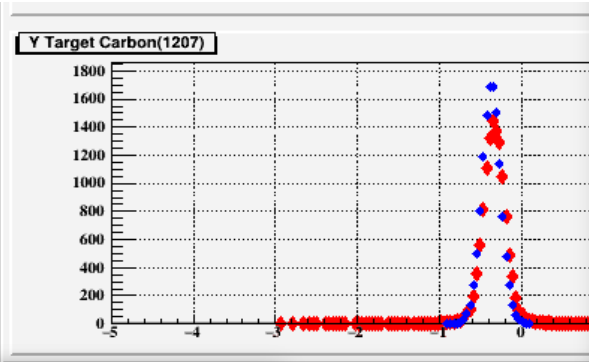

Raster off, Carbon foil, $p_0=2.14\text{GeV}$,
 $E_b=6.14\text{GeV}$, $\theta=17.005$ from dec.

Run 821 (dec) ; 1207(kin 1) ; 1233(kin2) ztar offset = 0.8 cm

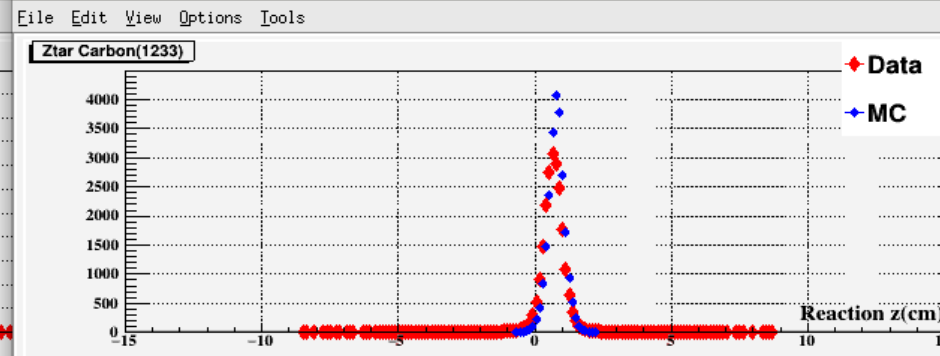

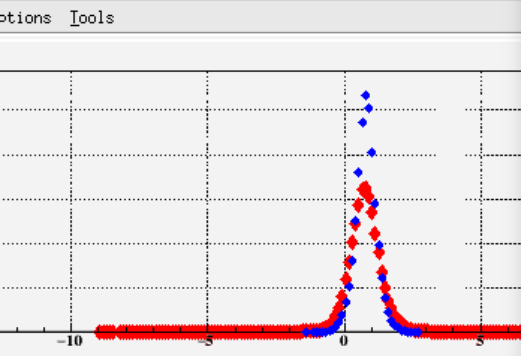

Canvas 4 for run 821

Canvas 4 for run 1207

Canvas 4 for run 1233

Canvas 4 for run 1279

Moving Forward

- Determine Y offsets for each kinematic
- Determine if the after transformer failure kinematics seem similar issue as the kin4 (2568 run)
- Update the Monte carlo with a way to implement the offset on kinematic basis.
